THE FUNCTION OF THE STATE HOSPITAL AS AN EDUCATIONAL AND SOCIAL AGENCY

WINFRED OVERHOLSER, M.D., Sc.D.

Superintendent, Saint Elizabeths Hospital
WASHINGTON, D. C.

In selecting a subject which might be of interest to a group of physicians concerned with hospital standards and with medical education, it has seemed that some consideration might well be given to a group of institutions which constitute one half of the hospital beds of the entire country, namely, the state mental hospitals. These institutions deal with a field of medicine which has developed rapidly during the last quarter century and which has become more and more clearly recognized as closely related to general medicine and to the other specialties. Furthermore, they are of interest as being predominantly public in ownership and operation, less than 2.5 per cent of the mentally ill of the entire country being cared for in private hospitals.

Although instances of mental disorder have been recorded from the dawn of history, and although this form of disease was the subject of consideration by Hippocrates and Galen, during the dark ages, the middle ages, the Renaissance and even a large part of the modern period, the subject was considered to lie much nearer to the field of philosophy than to that of medicine. The victims of such disorders were either looked on as witches and executed or were classed, as in the early days of this country, along with drunkards and other types of so-called criminal. In the American colonies drunkards and paupers and the "furiously mad" were classified together not only in the same statutes but in the same kind of institutions; namely, jails. Those mentally ill who were not "furiously mad" were merely allowed to wander at large or were warned out from town to town. It is probably no exaggeration to say that much of the so-called stigma which exists in the care of the mentally ill today is a relic of this attitude of the early laws. It was not until 1773 that any of the colonies made official and public provision for the mentally ill in the establishment of a state hospital at Williamsburg, Va. Indeed, in the early 1840's, when Dorothea Lynde Dix started her astonishing career, a career which resulted in the establishment or enlargement of over thirty mental hospitals in this country, there were not over five public mental hospitals in existence in the whole of the United States. By 1870 the number had grown to fifty public and sixteen private hospitals, with a population of about seventeen thousand, and approximately ten thousand

admissions a year. Although an attempt was made to be humane and decent in the care given to these patients, the custody was essentially nontherapeutic in purpose, and the institutions were generally known as asylums; that is, places of refuge. Their growth since that time has been little short of staggering.

There are at present, according to the United States Census¹ (for 1938), over five hundred mental institutions in this country, among them one hundred and seventy-six state hospitals, two federal, twenty-six Veterans Administration, sixty-seven county and city, seven psychopathic hospitals and probably about two hundred and fifty private institutions of greater or less size. In the state hospitals alone the population at the beginning of the year 1938 was 424,028, and during that year there were in round figures 106,000 admissions, nearly 58,000 discharges and 31,000 deaths. The actual cost of maintaining these institutions during that period was over \$113,000,000, without regard to the cost of permanent construction or the loss to the community in the earning capacity of the patient. Of late there has been a rather rapid growth in the number of patients cared for in the mental hospitals of the United States, the rate per hundred thousand of general population having risen from 241.7 in 1923 to 361.7 in 1939, an increase of 45.5 per cent. This increase has naturally caused great concern in some quarters. Extensive building programs have been undertaken in several states, and a few have, under the economic lash, newly discovered the system of family care in use in one state since 1884 (Massachusetts) and developed at Gheel, Belgium, since the Middle Ages. Many factors are involved, among which the actual incidence of mental disorder in the community is only one. Among these factors may be enumerated, first, the attitude of the public toward the institution and toward mental disease in general; second, the existence of adequate facilities; third, the existence of laws which do not render admission to the institution unduly difficult or attended by public humiliation; fourth, the economic situation of the families or relatives; this often has a bearing both on the patient's commitment and his early removal from the institution before he is entirely self supporting. Other factors, such as the degree of urbanization and the proportion of elderly people in the community, must also be considered.

As to the types of mental disorder, the campaign against syphilis has unquestionably caused a reduction in the admissions for dementia paralytica. In the case of the alcoholic psychoses a considerable reduction took place at the onset of prohibition, but there has been a steady rise since 1921, with a result that we are now at approximately prewar levels (4.5 per cent of first

1. Patients in Mental Institutions, 1938, Washington, D. C., Government Printing Office, 1941.

admissions). The most striking increase has taken place in the arteriosclerotic group, a group which has shown an increase in ratio which is almost fantastic; indeed, from 1912 to 1936 the rate grew from 7.7 to 49.0 per hundred thousand of general population over 40 years of age, an increase of 536 per cent!² It has been well demonstrated that the liability to develop mental disease increases very rapidly after the age of about 50 and indeed that the incidence of mental disorder roughly parallels the mortality curve. The proportion of aged in the population is showing a rather rapid rise. From 1900 to 1935 it rose from 4 to 6 per cent (persons over 65), and it is estimated that by 1980 approximately 14 per cent will be in the upper age bracket. As a result, an increase in the senile and arteriosclerotic groups is fully to be expected. What effect the present war will have on the incidence of mental disorder cannot yet be predicted. The experience in England has indicated no substantial change in the admission rates to mental hospitals so far, but it is altogether too early to say what the ultimate effect of a total war may be on the mental health of any nation.

It is needless to point out that different states have different standards. This fact is well illustrated by the statistics relative to mental hospitals in various states. The effect of low appropriations, of the backwardness of legislatures in furnishing facilities and of the varying methods of admission is well illustrated, for example, in certain statistics. The average annual cost of maintenance per capita in 1938 was \$297.13, with variations from \$427.86 (Massachusetts) and \$411.65 (New Jersey) to \$117.82 (Kentucky) and \$146.75 (Mississippi). The average number of patients per hundred thousand of general population was 344.3, the greatest being 544.8 (New York) and 541.1 (Massachusetts), the least 179.1 (New Mexico) and 183.2 (Idaho). The crowding (average 9.4 per cent) ranges from 31.8 per cent (Missouri) to an excess of beds of 15.9 per cent in Rhode Island. Finally, the number of patients per employee (average 5.7) varies from 3.2 (District of Columbia) to 11.4 (Idaho).

METHODS OF ADMISSION

Reference has been made to the methods of admission to state hospitals. It is interesting to note that until 1872 admission to mental hospitals was about as simple as to any other institution. This was undoubtedly as it should be, and, as a matter of fact, abuses were practically unknown. In 1867 the famous case of Mrs. Packard received much attention in Illinois, with the result that a wave of legislation requiring mandatory jury trial swept over the country.³ It was alleged that many patients were, to use the colloquial phrase, railroaded, and that, in order to safeguard the occasional individual against such a fate, trial by a jury was necessary. Probably little argument is required to the effect that the haling of a mentally ill person into a criminal courtroom before a jury of laymen with a public recitation of the symptoms is humiliating to the family and psychologically most painful and harmful to the patient. I am glad to say that nearly all states have retreated from this extreme and barbarous state of affairs, the latest jurisdiction being the District of Columbia. Two states, Mississippi and Texas, still require a jury trial,

in the latter state only if the patient is to be retained in the hospital over ninety days.⁴

All states but fourteen and the District of Columbia provide for some form of voluntary admission, although several of the states which have such laws on the books do not use them for one reason or another. The desirability of permitting a patient to enter a hospital without adjudication should be obvious and has been to most of the progressive jurisdictions. In eighteen other states some temporary or emergency admission, without any form of court order, is permissible. This is an extremely important point. In most states the form of adjudication is relatively informal and at least is taken care of in the absence of a jury and in chambers if a judge has to enter the proceedings. The fear of railroading is one of those bogies which dies hard. There is no reason why any such fear should exist provided adequate inspection and supervision of the mental hospitals of a state is provided for by law in the form of a department of mental diseases or some supervisory body of that nature. So far only one state, namely Pennsylvania, has made sufficient progress to strike out the obnoxious words "insanity" and "lunacy" from its law relating to the mentally ill. It is an unfortunate fact that a recent study showed that 64 per cent of the patients taken to mental hospitals are still taken there by the sheriff or police and that 29 per cent are held in jail pending such transportation. Thus we can see that in spite of the advances which have been made in the standards of mental hospitals the legal procedures have lagged considerably behind what is best for the patient. For those who are interested in the standards and the practices in the various states, mention may be made of the Study of the Public Mental Hospitals in the United States 1937-1939, published in 1941 by the United States Public Health Service as supplement 164. This study reports the work of the Mental Hospital Survey Committee, a joint agency established in 1936 by the American Psychiatric Association, the National Committee for Mental Hygiene and the United States Public Health Service, which has made a survey of most of the mental hospitals in the United States. The study is an extremely valuable collection of reliable data compiled by a disinterested group.

DEVELOPMENT OF PSYCHIATRY

In the period during which hospitals have been developing in size and in facilities, psychiatry has been developing as a specialty of medicine. In the early days the members of the asylum medical staff were looked on askance by the general medical profession and were considered as being out of the stream of general medicine. It was not until the turn of the present century that psychiatry as a separate discipline really began to take shape, and even then the psychiatry was essentially the institutional variety. With the epoch making work of Freud, however, the relationships of psychiatry to the neuroses (previously thought to belong in the field of the neurologist), to the behavior disorders of children, to the delinquent behavior of adults and, indeed, to the minor difficulties of everyday life, as well as to various types of physical manifestations of emotional conflict, began to be recognized. Interest in the treatment in the institutions was one of the first developments, but subsequently the outpatient departments developed, child psychiatry has made rapid progress, forensic psychiatry

has been recognized as a specialty, and even more recently we have come to hear much of psychosomatic medicine. Indeed, one of the refreshing developments in modern psychiatry is the recognition on the part of the internist, the surgeon and the practitioner of the various specialties that a very fair proportion of the complaints which are brought to him for care are primarily psychogenic and due to the emotional conflicts of the patient rather than perhaps cases for drugs or for operative procedures.

With these developments has come a recognition that the staff which allows only one physician to 400 or 500 patients is hopelessly inadequate. There has also come recognition of the need of training, of the need of medical libraries and the development of the various auxiliary services, such as clinical psychology, nursing, occupational therapy and social work. In the medical schools an increasing interest has been taken in the presentation of psychiatry to the students as something which is living and intimately related to general medicine, rather than a freakish specialty instruction in which has to be endured. The American Psychiatric Association, through the chairman of its Committee on Psychiatric Education, Dr. Franklin G. Ebaugh, and with the assistance of the Rockefeller Foundation, has accomplished much in the postgraduate training of physicians and in the training of medical students. Courses in medical schools have been substantially increased in length and in the variety of the problems presented to the students, with the result that the present day medical graduate has a far better grasp of the possibilities of psychiatry than did his fellow of twenty-five years ago.⁵ Progressive mental hospitals have recognized that those trained in them are not the only ones who profit. The value to the hospital of maintaining a teaching program is reflected in the attitude of the senior members of the staff and indeed, in the entire personnel of the hospital, with the result that the patient benefits.

At present eighty state hospitals have been recognized and approved by the American Medical Association as suitable institutions for residencies in psychiatry. This has certain corollaries not only in the physical equipment of the hospital but in the numbers of personnel and their qualifications. It is the hospitals which carry on an active training program for the benefit of young and well trained medical graduates which are in a position to render the best service to their patients. That, after all, is the fundamental reason for existence of any hospital or hospital function. The interest in training procedures was vastly stimulated by the establishment of the American Board of Psychiatry and Neurology in 1934. This board, which certifies specialists in psychiatry and neurology, scrutinizes closely the type of institution in which the applicant has had his psychiatric training. No longer is it sufficient to give the new doctor his keys and tell him to "make rounds"; active instruction and guidance are now required in order that the full benefit of the wealth of clinical material in the state hospital wards may be realized. This scrutiny in itself has done much to stimulate the hospitals to improve their standards of instruction of junior staff members.

At one time many mental hospitals had training schools for nurses, but, on account of the activities of some of the national nursing associations, many of these

training schools had been forced out of existence when the present emergency arose. At the present time hospitals are being encouraged to reestablish schools in order to meet the demand for nurses. Many of the better hospitals, which were more firmly endowed financially, have continued their training schools; as a matter of fact there is every reason why the graduate of a training school in an amply equipped mental hospital should in many ways be a better nurse for her experience with mental patients than the one who has had experience only in a general hospital. In fact, the tendency is growing for the general hospital training school to require affiliation with a mental hospital as part of its course. In addition to training medical students, residents, clinical psychologists and nurses, a number of hospitals are utilized in connection with the training of social workers, occupational therapists, dictitians and theological students. The value, indeed, of the recognition by the clergyman of the early symptoms of mental disorder and the need for treatment by a psychiatrist is being widely recognized today in theological schools. With the growing interest in the mental hygiene aspects of teaching, the facilities of the mental hospital might well be made available to teachers' colleges. Likewise, as a scientific approach to the problems of delinquency gains momentum these institutions may well take a part in the training of police.

STANDARDS

Some of the standards for mental hospitals which have been set by the American Psychiatric Association and are today generally recognized may be briefly considered. These standards have been set up as a result of many years of experience of conscientious state hospital administrators. That they do not receive universal acceptance is unfortunately the case. They are, however, approximated by the more progressive states, and, indeed, the number of states which fall lamentably below these standards is, fortunately, fairly small. The first qualification, which might well be considered by some states, which shall be nameless, is that the chief executive officer must be a well qualified physician, an experienced psychiatrist, whose appointment and removal shall not be controlled by partisan politics. As a corollary, all the persons employed at the institution ought to be subordinate to him and subject to removal by him if they fail to discharge their duties properly. As a second corollary the positions of administration of the institution must be free from control of the purpose of partisan politics. It is peculiarly true of mental hospitals that every activity of the institution affects in some manner the welfare of the patients. It is for this reason that we find the requirement of a psychiatrically trained physician as head, the superintendent to have control not only of the medical care of the patients but of the general policies of the hospital, including purchases, the kitchens, the farm and other activities. In at least one state (Massachusetts) it is required that the superintendent shall be a diplomat in psychiatry of the American Board of Psychiatry and Neurology and that he shall have had four years of administrative experience in a mental hospital. In some states, however, it is sufficient that the superintendent shall be friendly with some influential politician, and there are instances of nonmedical heads of such institutions or cases in which the steward or purchasing officer is not appointed by the superintendent or is even coordinate with him. Dual or lay control of a mental hospital jeopardizes the welfare of the patients.

5. For a detailed study of this subject see: Ebaugh, Franklin G., and Rumer, Charles A.: *Psychiatry in Medical Education*. New York City. Commonwealth Fund, 1942.

As for staff (the proportion of physicians to total patients), there should be not less than one to one hundred and fifty, in addition to the superintendent, and to the number of patients admitted annually not less than one to forty. There must be dentists, a staff of consulting specialists, an organized medical staff, suitable working facilities for the staff and carefully kept clinical histories. Suitable classification of the patients is, of course, essential, as is the existence of a laboratory, x-ray apparatus, a working medical library and suitable treatment facilities. The existence of outpatient clinics and an adequate force of trained social workers are called for, as well as an adequate nursing force of a proportion not less than one to eight. Such facilities are expensive, but in the long run they are a good economy to the state, for they mean early and adequate treatment of the patient, with corresponding likelihood of early restoration to the community and to a useful economic place.

OTHER FUNCTIONS

I have reviewed briefly some of the functions of the state mental hospitals, with particular reference to education and to the welfare of the community. It would be interesting, if time permitted, to consider some of the other possible functions of a state hospital. The state hospital should serve as a focus of the mental hygiene activities of the entire community. Nothing has done more, perhaps, to break down the local distrust of a hospital than the existence of outpatient clinics, both for adults and for children, maintained by the hospital, as is the case in many states. Still another function which has been extremely valuable has been the rendering of service to schools in examination of retarded or problem children, and to the court, under the Briggs Law of Massachusetts and the Desmond Act of New York, for the examination of persons coming up for trial. In the latter activity the hospital staffs have an excellent opportunity not only to learn much of the reasons for adult behavior but also to interpret to the court and to the public a more reasonable and understanding attitude regarding what is generally denominated as crime. Finally, in speaking of educational facilities we should not forget that the existence of the state hospital and its entire history represent a chapter in the education of the general public in an attitude toward mental disorder which is one not of fear, not of distrust of the institution, of the psychiatrist and of the afflicted person, but one which recognizes mental disorder as an illness which calls for sympathy, encouragement, understanding, and intelligent and trained treatment.

A Game with Ideas.—The teacher and the student likewise play a fascinating game with ideas in the classroom. The teacher rises to his feet to expound noble ideas which it took him years to discover. The student respectfully commits them to his notes. The teacher urges the student to become acquainted with other noble principles which are to be found in the textbook. The student faithfully endeavors to ascertain which of the two sets of principles is most likely to be favored on the tests. Toward these he exhibits, for the time being at least, an unmistakable attitude of devotion. But when the final examination is over he sells the textbook for enough cash to hitch hike home and kindly returns the ideas, as good as new, to the place whence they came. With respect the professor welcomes them home, imagining that they have been somewhere, and sets about giving them new clothes for another journey of the same kind.—Terry, Paul W.: *Some Reflections on Ideas*, *Assn. Am. Coll. Bull.* 26:257 (May) 1940.

THE WAR, THE COLLEGES AND FEDERAL AID

WILLIAM B. MUNRO, PH.D., LL.D.
PASADENA, CALIF.

The war has brought the universities and colleges of the United States face to face with serious problems. Student enrolments in the graduate and professional departments of many institutions, with the exception of medical schools, have seriously declined. With the downward extension of the age groups, as provided in recent amendments to the Selective Service Law, the junior and senior classes in undergraduate departments are certain to be similarly affected next autumn. And many prospective freshmen will doubtless find jobs in industry and give up the idea of entering college until after the war, which means that most of them will never enter at all.

It is true, of course, that efforts will be made—they are already being made—to maintain enrolments by relaxing the normal requirements for admission, by carrying on instruction through the summer and by shortening the time required for graduation. In some coeducational institutions the quota of women students is being raised above the usual limitation. These endeavors to keep the student body up to par may be in some measure successful; but if educational administrators are wise they will prepare for a substantial reduction in the attendance at their institutions during the next couple of years.

In the endowed institutions this means a serious decrease in the revenue from tuition fees at a most inopportune time, namely, when income from endowment has dropped by reason of the decline in interest rates and when the burden of increased taxes is making it more difficult to get financial help from the alumni. The state universities are more fortunate, for the moment at least, in that they are not dependent to any large extent on student fees or endowment income, but if their enrolments fall off it is not improbable that the state legislatures will feel justified in trimming educational budgets accordingly. Heavy demands for other expenditures, owing to the war effort, will encourage them to do this.

In any event the colleges should make up their minds to tighten their belts for the duration, and this is not going to be easy to do. Buildings have to be kept up, and it is costing more to maintain them than formerly. Wages of janitors, groundsmen, clerks in the administrative offices and other college employees are being forced skyward by competition for workers from outside. Likewise the cost of food in the college dining halls and of service in the dormitories is steadily rising. Laboratories cannot function without supplies, and these are now costing more. The size of the instructional staff will doubtless be reduced by the calling of some teachers into the defense services, and savings can be expected in that direction; but it is unlikely that this retrenchment in faculty payrolls will go very far toward solving the whole problem. Higher education, like everything else, is going to be at higher cost.

Caught in this dilemma between rising outlays and declining income, the colleges will be sorely tempted to follow the procession of supplicants to Washington.

Read before the Thirty-Eighth Annual Congress on Medical Education and Licensure, Chicago, Feb. 16, 1942.

They will feel that the federal government ought to recognize their plight and do something for them, either by an arrangement which would defer certain groups of students from induction or by grants of financial aid to tide them over. And why should not the federal government be asked to help the colleges by grants-in-aid? They are institutions of public welfare, and there is very little in the way of public welfare effort which the federal government is not being asked to subsidize in some way, direct or indirect. A few years ago these petitions were presented as a way of softening the hardships of an economic depression; today federal aid is being sought with equal urgency as a means of tiding over the dislocations of war prosperity.

The fact is that our people have been only too well schooled in the habit of lifting up their eyes to Mount Sinai on the Potomac—the hill from which cometh their aid. There was a time, not so long ago, when the states and local communities expected to pay for their own public welfare enterprises, including their educational institutions, and to be content with what they could afford. That day seems to have gone by. Even though the national government is now faced with the largest budget in all history, it will not be relieved from the importunities of those who want benefits for themselves in the name of maintaining the national morale.

STATE AID FOR SCHOOLS

If our institutions of higher education seek aid from the national treasury they will have both precedents and arguments to support them. Such assistance, if given, would simply be the culmination of what has been developing in the whole field of American education for a long time. The arguments supporting it are merely an extension of those which, for many years, have done service in relation to the public schools. Our first public schools, grammar schools they were called, began as community enterprises. They were wholly supported out of local taxes, and they received no other financial support until the opening of the West created a new problem.

In these new areas it became apparent that many of the pioneer communities, when left to themselves, either set up no elementary schools at all or provided very inadequate ones. Children on the frontier were growing up in illiteracy. Consequently the territorial and state governments in these areas found it necessary to make the establishment of grammar schools compulsory and often to provide money as a means of enabling the poorer settlements to comply with this requirement.

This, in due course, proved to be merely the onset of what grew into something approaching a nationwide policy. State aid to needy localities developed into state aid for all elementary public schools, then for high schools as well and finally in some cases for junior colleges on the basis of their average daily attendance. The original subsidies were defended as a means of "equalizing educational opportunity" as between richer and poorer communities; the newer practice of state-wide subsidization was not largely inspired by any such equalitarian philosophy but by a desire to lessen the load of taxes on real estate, especially on agricultural land. When schools have to be supported from local taxes, the property owner bears virtually the whole burden; but by state subsidies a part of the load can be shifted to the payers of income taxes, franchise taxes, inheritance taxes, sales taxes and other state

levies. It is not surprising, therefore, that the policy of state aid to local schools has had its greatest development in the agricultural states.

FEDERAL SUBSIDIZATION

The Constitution of the United States is silent with respect to public education. Its intent was to leave this responsibility to the states. And in large measure the states accepted this obligation until the economic depression of the recent thirties proceeded to break down the historical division of responsibilities between the federal and state governments. Literally billions of dollars were distributed by the national treasury to the states for all sorts of things and there seemed to be no reason why education, lower and higher alike, should not claim its share. Old arguments were brought forth to do new service, but in a higher range and on a wider scale. Federal aid to the universities and colleges began to be urged, and is still being urged, as a means of equalizing educational opportunity, not merely as between states or communities but as between individuals, by giving every young man or woman, rich and poor alike, a chance to secure a college education.

Momentarily, this campaign for a general subsidization is in eclipse as the result of the pressure on the federal treasury for defense expenditures; but its place has been taken by more restricted proposals tied up with the national emergency. To the extent that the shortening of the usual time required for graduation has put the colleges to some greater expense, it is now argued that the federal government should assume the extra cost, whatever it is. Likewise, if the colleges keep functioning right through the year, this will obviously be hard on those students who have expected to pay their way, in part at least, by earning money during the long summer vacation. So it is suggested that the federal government come to the aid of such students by giving them money or by lending it to them without interest.

Of course there is much to be said for emergency aid along the foregoing lines. But the danger is that any plan of subsidization devised for the emergency will be continued as a permanent feature of federal finance long after the emergency has passed. There are few things more tenacious than governmental subsidies once you begin the practice of giving them for any purpose and under any circumstances.

COMPETITIVE SCHOLARSHIPS

This idea of asking Congress to underwrite a college education for every one would have seemed strangely fantastic a generation ago, but there can be no blinking the fact that it has gained support from many influential quarters in recent years. Two chief arguments are used in its support—one educational, the other financial. Compressed into a sentence or two, the educational argument runs this way: If the country is to remain a democracy it must maintain the principle of the *carrière ouverte* by giving all its young men and women an equal opportunity to become leaders. This it can do only by making higher education a possibility, not merely for those whose parents can afford it, but for all qualified young men and women irrespective of their economic status.

The objective is to steer more students into the universities and colleges, when there are already more of them there than deserve to be. This is proved by the fact that about half of those who enter never stay

to graduation, while a sizable proportion of those who do become graduates are still uneducated. When they forget what they have memorized, not much will be left. Many of them, after four years of immersion in the collegiate atmosphere, remain illiterate to a degree, even with a degree. They are the handiwork of higher education—but higher than what? Higher, in some cases, than their intelligence warranted.

The slogan "equal opportunity for all" is a popular one. As applied to college education, however, it merely reduces a complicated problem to engagingly simple terms. Not all young people are able to profit equally by equal opportunity. Every teacher knows that many of them reach the point of diminishing returns in formal education before they arrive at the usual age of college entrance. For such persons the best education is vocational training, either for a job or at one. Too many young Americans are already sleeping through lectures when they ought to be awake at a work bench.

The proposal to use federal money in order to extend opportunities for a college education over a broader constituency would not make this situation better. It puts all the emphasis on quantity—more colleges and bigger ones. What we need is emphasis on quality—fewer colleges and better ones. There is already lots of room in the colleges of the United States for every one who is qualified and willing to profit by what these institutions have to give. You will hear averments to the contrary, but it is nevertheless true that there is hardly a college in this country, from Tusculum to Tuscaloosa, which is turning away any meritorious applicants today. Most of them, as a matter of demonstrable fact, are actively campaigning for more students, especially for more male students, in the endeavor to keep their budgets balanced. They have "waiting lists," so they say; but in many cases these are lists of students for whom the college is waiting.

If federal aid is ever to be made available it should not be by aiding the colleges to attract more low voltage youngsters. The aid should be by way of competitive scholarships whereby any boy or girl of exceptional capacity but of slender means would be enabled to attend any college of his or her own choosing. Such students would help to raise the intellectual level of the student body. They should be freely permitted to make their own choice among institutions, for although many of them might choose to enter what educators sometimes designate as "second rate" colleges there is no college in the United States, however weak or poor, at which a bright, earnest student cannot get a good education if he sets out to do it. And by the same token there is hardly a college in the land, however rich and strong, at which a dull witted, lazy student cannot avoid getting one if he is so minded. It is the student rather than the institution that determines the worth of the educational process. That being the case, it is surprising that colleges, on the whole, give so little attention to their methods of instruction and so little to the selection of students who can profit by any instructional method.

REDISTRIBUTION OF WEALTH

The other argument in favor of federal aid to the colleges is financial. Federal subsidies are advocated as a measure of fiscal reconstruction—as part of a general plan for the redistribution of wealth and income. According to a recent publication of the National Advisory Committee on Education, federal aid would place

"a larger share of the tax raising responsibility on the level of government which . . . is in the best position to distribute its taxes equitably, efficiently, and with a view to their economic effects."

There, in one sentence, is the cloven hoof that betrays one type of sponsorship for greatly increased federal largesse to the states. The national government can levy high taxes on corporate profits, inheritances and individual incomes, thus obtaining huge sums of money which can be distributed "with a view to their economic effects." This, of course, is an ingratiating way of saying that the federal government should use its taxing power to compel a redistribution of wealth under color of promoting the interests of education. Much of the support for federal aid to higher education comes from those who care little about the purpose for which the money is being expended so long as it serves to take from those who have and give to those who have not.

But it does not often profit either men or institutions to accept what they have not earned. There is an Italian proverb which the colleges will do well to remember if they are invited to dip into the national treasury: *Dannoso è il dono che toglie la libertà* (Curséd is the gift that taketh away our liberty). For whatever may be hoped to the contrary, federal aid will inevitably lead to federal guidance, discipline, restraint and control. Those who hold the purse will wield the power. That must be the case, for it would be a negation of responsible government if public funds were permitted to be spent without control by the authorities who make the appropriations. Expenditures without control are bound to be wasteful, as every one knows; there is indeed no greater incentive to wastefulness than to let authorities, whether public or private, spend at their own discretion money which they have been at no pains to raise.

When any one argues, therefore, that the federal government could aid the colleges by subsidies without placing any constraint on their freedom, he is disregarding the lessons of experience in this field. We know only too well what has happened in the case of federal aid to the states in the matter of highways, public health and vocational education. At the outset the national authorities prescribed nothing more than the main objectives and the general standards. Then, little by little, the terms on which the subsidies could be obtained were defined with increasing strictness. In this connection it is significant that the National Advisory Committee on Education, which has been an ardent supporter of federal aid to education, recently urged that a revision of the federal statutes be made in order to "free vocational education from many burdensome restrictions imposed from federal sources" and to "end interference with local school administration."

THE OUTCOME

Federal subventions make for centralization of control, always and everywhere. Centralization of control, in turn, leads to an insistence on uniformity through the setting up of procedures which all are expected to follow. Howsoever excellent these procedures may be, they discourage experimentation and diversity. In the end there is apoplexy at the nerve center and paralysis at the extremities. The division of power and responsibility between the national, state and local governments in the United States is not a mere matter of geographic convenience. It is a democratic concept based on the proposition that power and responsibility should be widely decentralized as a safeguard to local

freedom of action. It is a concept which looks on differences of action and opinion as something to be encouraged, not repressed—and our universities exist in order that such differences may find a haven of tolerance. Today the world is moving at an alarming pace toward a regimented intellectual economy, a way of life in which there is no place for dissent or nonconformity. Even in Great Britain and the United States, where democracy is still holding its battlements, there are noticeable trends in the same direction.

Before listening to the suggestion that they balance their own budgets by more heavily unbalancing the national one, the colleges should consider whether they might not be accepting the deadly gift of Minerva, the wooden horse of Troy. The tradition of freedom which the endowed educational institutions of America have built up during three hundred years is a pearl of great price. It should not be surrendered, even though the alternative is near starvation. No doubt such a surrender will never be made by them wittingly. But there is some danger that it may be done without realizing what long range implications are involved. "Early and provident fear," as Edmund Burke once said, "is the mother of safety." Uncle Sam might prove to be a kindly overlord—but an overlord he would be all the same.

California Institute of Technology.

WARTIME PROBLEMS OF THE PUBLIC HEALTH SERVICE

THOMAS PARRAN, M.D.

Surgeon General, U. S. Public Health Service
WASHINGTON, D. C.

The physicians of the United States face a task of historic importance. It is a rearguard action as one considers the net saving of life and decrease in suffering. It is in the front line of attack with regard to its potentiality to strengthen the arm of the fighting forces and speed the day of final victory.

One point must be made clear in the beginning: the Medical Corps of the Army and Navy have responsibility for the medical care of the personnel of the armed forces. The ratio of physicians to the strength of those forces must of necessity be larger than the ratio of physicians per thousand of the general population. The Public Health Service, working in partnership with the state health authorities, has responsibility for general health conditions of the whole remaining population—more than one hundred and twenty millions—even when the whole military and naval force is mobilized for all out final drive to victory. In addition to holding the lines against preventable disease, it is necessary for the public health profession, working in close harmony with the private practitioner, to build more strongly than ever before that condition of positive health without which our population can neither sustain itself in time of trouble nor attain the tremendous production required to supply our fighting forces and those of the United Nations with the munitions of war.

The Public Health Service also has many special problems arising out of the war. The load of clinical care in our twenty-nine hospitals mounts steadily with the constant increase in the Coast Guard and the merchant marine. The industrial hygiene service must

keep pace with the needs arising from high speed assembly lines, which will employ some fifteen million men and women within the year. Great Britain learned that it is urgently necessary to have the full time services of a trained industrial physician in every large plant. Less than one seventh of our workers have that service now.

St. Elizabeths Hospital will face demands beyond any in its history. The increase in the population of the District of Columbia is of phenomenal proportions; moreover, the hospital is required by statute to care for the mentally ill of both the Army and the Navy. New and urgent tasks have been laid on the research division of the Public Health Service, the National Institute of Health, to meet both industrial and epidemic hazards. Establishment of an Emergency Medical Service, under the auspices of the Office of Civilian Defense, obviously must be given first priority in the vulnerable areas. It is necessary to perfect every detail of these plans now. There will be no time when the bombs begin to fall.

Our greatest specific new responsibility arising out of wartime conditions, however, has been due to the vast shifts of population. Military camps, industrial expansion, new shipyards, arsenals and other reallocations of national power to war effort are turning villages to cities almost over night. Acute problems of sanitation, public health, including venereal disease control, hospitalization and medical care are created thereby.

We are all agreed that no effort should be spared in securing for the Army and Navy the medical personnel needed increasingly for the care of our soldiers, sailors and marines. The Procurement and Assignment Service, under the able chairmanship of Dr. Frank Lahey, provides the method of using to the best advantage the available physicians and dentists of the country. Every governmental agency is cooperating fully with that office.

It is clear however that, when army and navy needs have been met in full, a huge task remains for protection of the civilian population and for the smooth functioning of specific war responsibilities of that population. As regards the total number of doctors involved, public health is relatively a small specialty of medicine. Our best estimates show that the number of full time physicians employed in the federal, state and local public health work approximates three thousand five hundred. Another thousand qualified doctors are needed now to fill vacancies caused by the calling of reserve officers in states and localities to active duty and to meet new needs as previously indicated.

The numbers of men needed are far less significant than the kind and quality of men and their special training. Unlike the Army and Navy Medical Corps, who need men essentially for clinical service, only a fraction of the doctors needed now by the Public Health Service, and almost none of those needed by the state and local health authorities, can be drawn from the private practice of medicine and put to work immediately without intensive special training. Public health skill of any one type (venereal disease is a good example), and there are scores of specific illustrations, requires the capacity to translate a doctor's clinical knowledge of disease into a system of control that will not only check the disease in the individual but protect the community against it, and it is most important that he have the capacity to put that plan of control into operation.

It is, perhaps, not clearly understood that the men in the regular commissioned corps of the Public Health

Service are commissioned by the President and hold status of rank, pay and retirement on a parity with regular medical corps officers of the armed services. We select them with rigorous care and find it most profitable to train them ourselves in the specific field for which their capacities best fit them, using fully the special training centers of universities and other medical centers.

One problem which has not been met is that of medical care in the areas whose populations are recently swollen by the influx of population for both military and industrial establishments.

Our specific information comes from three sources: Since November 1940, at the request of the state health officers, we have been conducting a sanitary reconnaissance in the defense areas by sending in teams of physicians and engineers to obtain first hand intelligence of the needs and available health resources. In addition, the defense housing projects administered by the Federal Works Agency have enlisted the Public Health Service in an advisory capacity, as proper housing is closely associated with the provision of basic sanitary facilities in these newly overcrowded areas and where the shortage of doctors inevitably comes to attention. We have found by preliminary investigation that the facilities for medical care in most of these areas are very poor; that the situation could become alarming in the event of epidemics. Also the Army has requested civilian physicians for housing projects located near Army posts, as the Army physicians have their hands full in caring for military personnel.

A major part of the problem, of course, is that of distribution. An announcement made last fall in THE JOURNAL and to one thousand approved hospitals urged all physicians interested in practicing in defense areas to get in touch with the Public Health Service. About five hundred doctors answered. These were followed up by questionnaire on their qualifications. There is now a list of about three hundred physicians who have signified their willingness to move, usually with some preference as to locality.

By means of this list, plus the findings from additional surveys, it is hoped that physicians can be gotten into areas that greatly need them. Where it is desirable, the physician can rent quarters in a defense housing project.

In supplying medical personnel for defense areas, the problem of licensure has already caused confusion and delay. These difficulties often could be overcome by prompt granting of reciprocity to qualified physicians desiring to transfer from one state to another, or by temporary revocable licenses pending qualification. I hope that the state boards of licensure will give serious attention to this matter with a view to speeding up the licensing procedure.

There are many competent physicians in the United States who have come to our shores as refugees. Many of these could be made immediately available for service in areas where the shortage is acute, if they could be licensed to practice. We should consider the possibility of combining self interest with hospitality and giving all these doctors who are qualified an opportunity to help meet the growing shortage of medical personnel.

It probably will be necessary for the public health schools to give shorter and more intensive courses to new medical recruits going into public health work. Some of the schools already have taken steps in this direction. I would venture to suggest also that the

medical schools of the country consider the possibility of intensifying their present courses in preventive and tropical medicine. A thorough knowledge of these subjects is a valuable asset to the large groups of recent medical graduates who will be going into the military and naval service, no less than a relatively small number going into public health service.

Because of the shortage of doctors, it will be necessary for various types of medical care to be diluted, for the doctor's time to be saved, by using in many routine technical tasks persons who are less well trained than those now engaged. This applies to laboratory procedures and to work in x-ray departments as well as to routines in the hospital wards and in the dispensaries and clinics. A great number of such technical personnel will need to receive intensive training.

Many thousands of nurses' aides are now being trained. Less attention has been given to the need for aides to technical personnel in other sectors. The need for them is none the less real.

This is total war; the civilian is at the front with the soldier. Civilian health and strength are as essential to victory as is the medical care of our armed forces. Needs are too urgent to permit half-way methods. Complete cooperation on the part of medical men throughout the country is the first requirement. By full use of every qualified doctor's ability, I am confident that the American medical profession again will meet effectively the supreme test. Public health takes on a new urgency. Heretofore we have sought health primarily for its value to the individual. Now we must attain it for the nation's security.

THE PRESERVATION OF HUMAN PLASMA

REPORT OF STUDIES WITH THE SULFONAMIDE COMPOUNDS

FREDERICK K. HEATH, M.D.

AND

WILLIAM D. PROVINCE, M.D.

NEW YORK

Between August 1940 and January 1941 in New York City the Blood Transfusion Association, in cooperation with the American Red Cross, prepared 6,151 liters of liquid human plasma for England.¹ Of this amount 8.5 per cent was found to be contaminated, despite the use of merthiolate in the concentration of 1:10,000. Because of this finding and the observations of Novak² and other workers³ in the field an attempt was made to investigate further the use of the sulfonamides in the preservation of blood plasma.

METHODS

Three separate series of experiments were carried out. In the first, from 12.5 to 20 cc. of pooled human citrated (0.5 per cent) plasma was placed in sterile tubes to

Dr. A. R. Dochez supervised this study and gave many helpful suggestions.

The human plasma was obtained through the New York chapter of the American Red Cross.

Financial aid was given by the Blood Transfusion Association and the Medical Division of the National Research Council.

From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

3. Harrington and Miles,⁴ Hunwicke,¹¹ Becart and Philippe.¹¹

which increasing amounts of various sulfonamide derivatives were added so that the final concentrations were 10, 20, 30, 60, 100 and 200 mg. per hundred cubic centimeters. Sulfanilamide and the sodium salts of both sulfapyridine and sulfathiazole were the compounds tested. Each drug was made up with sterile 0.85 per cent solution of sodium chloride into a 1 per cent solution; this was passed through a Seitz filter and the necessary amount was added to the plasma tube to bring about the drug concentration desired. Determinations

tion, was incubated at 37 C. while another set was kept in a refrigerator at 5 C.

Pour plate sampling was carried out weekly after thorough mixing, 0.1 cc. specimens added to 10 cc. of agar, or 10 per cent rabbit's blood agar in the case of the hemolytic streptococcus, being used. Finally, the pour plates were incubated for forty-eight hours or longer before being evaluated, since it has been our experience that under these conditions growth may not appear before forty-eight to seventy-two hours. The

of the sulfonamide concentration in random plasma tubes were made after three months, and it was found that the drugs were present in the original concentration.

To these tubes, then, and one or more controls for each variety of bacteria used, was added a known number of organisms as determined by the dilution-plating technic. The organisms used⁴ were hemolytic streptococcus strain cv203 and strains of Bacillus lactis aerogenes and hemolytic Staphylococcus aureus isolated from patients in the Presbyterian Hospital shortly before these experiments were undertaken. One set of such tubes and controls, securely stoppered against evapora-

results are recorded as the number of colonies per cubic centimeter of plasma-drug solution.

Our second group of experiments was essentially similar to the first. The drugs used were sulfanilamide, sulfapyridine, sulfathiazole and sodium sulfadiazine in concentrations of 10, 50, 100 and 200 mg. per hundred cubic centimeters. With the exception of sodium sulfadiazine,⁵ which was prepared by passing through a Seitz filter, the drugs were taken from stock, carefully weighed out and the necessary amounts added to 10 cc. tubes of plasma. Whereas at the higher concentrations of 100 and 200 mg. per hundred cubic centimeters the drugs at first remained undissolved, as evidenced by

4. Cultures were obtained through Misses Gladys Hobby, Barbara Mulliken and Margaret Sheridan.

5. Dr. David Bryce of the Lederle Laboratories, Pearl River, N. Y., supplied the sodium sulfadiazine.

a white precipitate at the bottoms of the tubes, they all went into solution during the first week. Determinations of the drug concentration in tubes chosen at random supported this conclusion. The organisms used were a strain of *Streptococcus viridans* isolated from a patient with subacute bacterial endocarditis who had received no chemotherapy, pneumococcus type I recently passed through mice and the same strains of *Staphylococcus aureus* and *Bacillus lactis aerogenes* as used previously. One cc. samples were taken weekly and added to 10 cc. pour plates of agar or 10 per cent rabbit

RESULTS

The first series of experiments are reported in tables 1 and 2. In the tubes stored at 37 C. (table 1) it will be seen that the hemolytic streptococcus failed to grow, even in the controls, despite two inoculums. This observation had been previously reported by Tillett.⁶ *Staphylococcus aureus* grew well for four weeks at concentrations of all drugs of 30 mg. or less per hundred cubic centimeters. With higher concentrations of the sulfonamides definite inhibition of growth was noted, but no consistently negative tubes were obtained.

blood agar. These were incubated for at least forty-eight hours.

The third group of experiments was done with 10 cc. samples of plasma containing sodium sulfathiazole in a concentration of 200 mg. per hundred cubic centimeters. In one experiment such samples were placed in uncovered Petri plates and exposed to air for periods ranging from five to one hundred and twenty minutes. Control agar and 10 per cent rabbit blood agar plates were exposed at the same time for thirty minutes. After exposure the plasma-drug solutions were placed in sterile tubes and kept at room, incubator or refrigerator temperature for a period of one week, during which time 1 cc. samples were incubated with 10 cc. of agar in pour plates for at least forty-eight hours.

Sampling at the end of ten weeks revealed that the organisms had died out in all tubes, including controls. The results with *Bacillus lactis aerogenes* were similar.

Table 2, showing the results in tubes stored at 5 C., indicates that no significant effect was obtained against either the staphylococcus, streptococcus or *Bacillus lactis aerogenes*. In this experiment the control tubes paralleled the test tubes except for the first week, at which time bacteriostasis was apparent.

Experiments of the second group are reported in tables 3 and 4. Here again at 37 C. (table 3) it will

be seen that growth of *Staphylococcus aureus*, while somewhat inhibited at the higher concentrations, was still present in most tubes after eight weeks, appearing in the sulfadiazine tubes, up to then apparently negative, after four weeks. This fact, plus the long period required for growth to appear in our pour plates in all these experiments, confirms the well recognized

inhibitory effect of the sulfonamides on bacterial growth and demonstrates the practical impossibility of one being certain of a bactericidal action. Thus, had the sulfadiazine tubes been discarded at the end of three weeks or had our pour plates been discarded after forty-eight hours, many more negative tubes would have been reported. Little growth was obtained with *Streptococcus viridans* and the pneumococcus in either the control or the treated tubes. With *Bacillus lactis aerogenes* some bacteriostatic effect was obtained in the treated tubes.

At 5 C. growth of *Staphylococcus aureus* was poor but persistent, despite the drugs. The other organisms failed to multiply in test or control tubes.

The last set of experiments (tables 5 and 6) indicates that the plasma exposed to air in the presence of a concentration of sodium sulfathiazole of 200 mg. per hundred cubic centimeters supported but little growth when the length of exposure was sixty minutes or less (table 5). However, as shown in table 6, the three drugs at concentrations of from 10 to 100 mg. per hundred cubic centimeters exposed to air for thirty minutes showed growth on the pour plates at all concentrations to the same extent as in control plates without a drug.

COMMENT

In 1939 Milan Novak⁷ in this country and Harington and Miles⁸ in England suggested that the sulfonamide compounds might be useful in the preservation of stored blood. Novak's first communication was followed by a second paper⁹ in which he definitely recommended the use of sulfanilamide in a concentration of 20 mg. per hundred cubic centimeters as a satisfactory preservative agent for whole blood over a period of ten days. However, although his tables show a bacteriostatic effect in many tubes, growth was present. The ability of the organisms to grow after a period of days remained. Thus, in the case of *Pseudomonas aeruginosa*, he states that not even a concentration of 100 mg. per hundred cubic centimeters is sufficient to

inhibit this organism beyond a fifteen day period. Hunwicke¹⁰ was also able to demonstrate bacteriostasis but similarly noted small growth persisting over a period of a month or more. From these data it does not appear to us that such a procedure would be safe for general use. In 1940 Bécart and Philippe¹¹ suggested the use of sulfanilamide in the preservation of plasma, and Novak¹² has also extended this method to the preservation of stored plasma. Dr. Novak states: "In actual routine clinical usage over a two year period the method has been found to be completely satisfactory regardless of temperature (4 C. to 24 C.) or duration of storage." We question whether this proves the efficacy of the method, since the last 7,364 consecutive phlebotomies done by the American Red Cross at the Presbyterian Hospital Unit in New York City,¹³ using the closed system of collection with no preservative, have been done with only 1 instance of contamination. Here again we do not feel that the data presented support the conclusions drawn.

Our own experiments indicate that the sulfonamide compounds unquestionably exert a bacteriostatic effect on some organisms. This is best shown in the tubes exposed to contamination by air in which at a concentration of sodium sulfathiazole of 200 mg. per hundred cubic centimeters very little growth occurred. On the other hand, when similar tubes were specifically contaminated with known organisms, growth was persistent. Because of the latter observation and the impossibility of controlling either the type or the extent of contamination, we believe that these agents are not sufficiently inhibitory under all conditions to make them safe preservatives for stored plasma.

CONCLUSIONS

1. The sulfonamide compounds tested have been found to exert some bacteriostatic effect in stored plasma.

2. This effect has not been sufficiently significant or consistent at the concentrations tested to recommend the use of the sulfonamide derivatives alone in the preservation of stored liquid plasma.

MEDICOLEGAL ASPECTS OF PHYSICAL MEDICINE

PREVENTION OF LEGAL CLAIMS AND HOW THE
PHYSICIAN SHOULD SAFEGUARD HIMSELF

JOHN S. HIBBEN, M.D.
PASADENA, CALIF.

As long ago as 42 B. C., Publius Syrus said "Many receive advice; only the wise profit by it."

Every member of the regular medical profession, general practitioners as well as the members of every specialty, uses either directly or indirectly physical methods in treatment. When he prescribes these methods, he assumes at once a medicolegal responsibility, just as he does in prescribing any other form of treatment.

Physical therapy, according to the Council on Physical Therapy of the American Medical Association, is a term employed to define the treatment of disease by various nonmedical and nonsurgical means. It comprises the use of heat, light, water, electricity, massage, exercise and climate.

There are certain definite indications for the use of one or a combination of several of these physical agents in the treatment of disease. However, to depend solely on these agencies, to use them in lieu of better proved methods or to employ them without first having thoroughly studied the patient from the standpoint of diagnosis is harmful practice.

By law a physician is bound to bestow such reasonable ordinary care, skill and diligence as physicians and surgeons in the same neighborhood in the same general line of practice ordinarily exercise in like cases. A physician, therefore, must follow established methods of practice, and should he depart from recognized remedies or methods of treatment or diagnosis he does so at his own peril and risk. Should such departure result in injury to the person so treated, the physician will be liable for damages, however good his intentions may have been—but this must be proved. The law does not exist which expects physicians to be infallible—allowance is made for the possibility of human beings to err.

A physician prescribing physical therapy may decline or refuse outright to render services if for any reason he should prefer not to do so. However, if he has agreed to do so he has assumed a contract and is liable for any damages which may result from failure to fulfill or complete his contract. On assuming or undertaking to diagnose and treat a condition, one contracts and agrees that he possesses a reasonable amount of skill and knowledge and that he will apply that skill with ordinary care and diligence.

What are the medicolegal aspects to be considered when the physician delegates some member of a family, a practical, undergraduate or graduate nurse or office attendant or physical therapy technician (registered or unregistered) to carry out his orders, whether verbal or written? Just as with the surgeon, the physician is responsible for any negligence on the part of the person to whom he has assigned a duty, even though she is employed and paid by the patient. It behooves him, therefore, to see that his instructions are fully understood and that they will be carefully carried out. If the work of the nurse is a part of the service rendered by the physician and this service is rendered in the absence of direction by him, he is liable. In a hospital, the physician must give specific, preferably written, instruction

to the nurse or technician, and a failure to do so might well give cause for action against him. He may order the application of a hot water bottle; if it is a class A hospital, he assumes that the proper heat has been used (120 to 125 F. as the temperature of the water put into the bottle). Though this is assumed to be familiar knowledge among nurses, the proper and safe way would be for the physician to write a definite order stating:

1. The part of the body to which the hot water bottle is to be applied.
2. Whether the hot water bottle is to be in direct contact with the skin or whether there should be intervening material.
3. A word of caution if the weight of some part of the body is to be resting on the bottle (undue pressure might cause a circulatory ischemia resulting in a burn or destruction of the tissue).
4. Length of application and temperature of the water put in the bottle, with respect at all times for the will of the patient. If he or she says the bottle is too hot—remove it.
5. The bottle should not be applied if the patient is unconscious or asleep unless there is adequate supervision.

The same principles apply in substance to the use of other physical therapeutic energies: hot or cold applications of water, infra-red lamps, bakers, electric heating pads, ultraviolet radiation, short wave diathermy, paraffin baths and other mechanical agencies. Any physician who does not know the nature of and the therapeutic application of and indications for the energy he wishes to prescribe is not qualified and should not order it. When it is prescribed, there should be a written order for its use. Patients are often sent to the physical therapy department of a hospital, or to the offices of lay technicians, with no order other than that they are to have some physical therapy. Here again I will say that a physician in prescribing for the patient agrees that he possesses a reasonable amount of knowledge and will apply that knowledge with care. In prescribing physical therapy it is assumed that he knows what form should be applied, and he should write and sign an order for this remedy just as he would be expected to do when sending his patient to a drug store for medicines. When a technician is left to administer treatment to the patient in the absence of instruction, it cannot be expected that the proper results will be secured; too much is left to chance. The patient will most likely become discouraged, and it is not surprising that so many finally land in the offices of the irregulars. After a few months the physician who has meant well enough may find himself called into court to answer charges of neglect.

A physical therapy department, whether in the hospital or out, should be in charge of a physician trained in physical medicine, and this physician should be assisted by registered physical therapy technicians. This would decrease medicolegal liability some 90 per cent and at the same time secure confidence on the part of the patient and divert the patient from the offices of the irregulars. A department run on such a plan would not be subject to the prejudice that is felt by many of the regular profession toward the therapeutic possibilities of scientific physical medicine. It is their confidence that the specialty of physical medicine wants; the confidence of the patient will follow. Happily, departments supervised in this manner do exist throughout the country, but there is need of many more.

I believe that the majority of medicolegal cases involving physical medicine are brought against members of the regular profession who merely dabble in physical

therapy and are not so often brought against the physician who specializes in part or entirely in physical therapy. This belief is substantiated by data obtained from Dr. L. J. Regan, chairman of the Committee on Medical Defense of the Los Angeles County Medical Association, who says that during the past ten years only about 6 per cent of all claims in Los Angeles have been in the field of physical therapy; it is interesting to note that the specialist is not often charged with damage, as is the general practitioner.

The foregoing comments are applicable to our daily physical therapy practice. The physical therapist is vulnerable, and unless he is cognizant of these potential dangers he is liable to suit. The physician would do well to adopt an attitude of defense and consider every patient as a potential legal case. By this I do not mean to infer that he must be belligerent—he may be as gracious as the occasion demands but at the same time not forget to be cautious.

GENERAL PRECAUTIONARY MEASURES

The subject of legal safety may be considered from the point of view of both general and specific treatment. Of utmost importance is a complete history. A complete physical examination should be made and laboratory and roentgen examinations when indicated. Each treatment should be charted under the date administered, together with the kind and length of treatment, any changes that might have taken place in the condition of the part treated and any other significant data. The type of treatment, together with its limitations, possibilities and probabilities, should be fully explained to the patient at the beginning; hasty, unguarded statements regarding the prognosis should be avoided. A definite understanding as to the number of treatments required should be determined, together with the cost and convenience in payment of the obligation.

Patients should have privacy and should always be properly draped with clean linens. The physician should solicit and always accept the patient's statement as to comfort; he should emphasize in advance that if the treatment is uncomfortable, even to the slightest degree, the patient is so to notify the operator.

It is wise, unless especially qualified, not to use equipment unless it bears the stamp of approval of the Council on Physical Therapy of the American Medical Association. Particularly is this true in regard to photochemical and thermoelectrical equipment. Equipment should be inspected regularly every six months or preferably oftener by a capable supervisor. A signed certificate by the person making the inspection, including the serial number of the apparatus together with the date of inspection, is of value. Should any court action arise, this certificate will serve as evidence that the equipment was in proper condition. Automatic timing devices serve as additional safeguards.

Before the patient leaves the table the area treated should be inspected and any irregularities noted. Also patients should be instructed to call the physician if anything of an unusual nature develops before the next scheduled visit. This last precaution may be taken in the presence of a technician.

PRECAUTIONS TO BE OBSERVED IN THE USE OF SPECIFIC ENERGIES

Thermal radiation is used when superficial local heating is desired for penetrating effects of approximately 3 mm. in the region of the far infra-red, as produced by heated objects: bricks, hot water bottles, electric

pads, hot water or paraffin baths, electric heater or carborundum filaments in a suitable reflector.

The average cutaneous temperature is about 89.6 F., and an increase of about 18 F. is about the limit to which the temperature of the skin can be raised without the formation of a bleb or blister. It must be remembered, however, that some parts of the body surface are much cooler, in which case there is more latitude. To avoid injury to tissues one should keep in mind the temperature at which the various thermal modalities may be used. Burns will occur if there is an excessive absorption of thermal energy, and the final criterion is the patient's comfortable sensation to heat. With regard to thermal treatment one should express oneself in terms of degrees of heat; with the patient the word burn should never be used, nor should it be used in court—a better term would be counterirritation. Before treatment is begun, one would do well to inquire as to previous treatments—roentgen rays, various chemical substances or drugs taken internally—because of possible narcotic effects or because of a possible idiosyncrasy or allergy.

The Elliott machine, which circulates hot water through rubber applicators, used principally in body cavities, requires special training and experience for its safe use.

A hot air apparatus, Council accepted, has a rubber bag through which hot air circulates and is used in heating body cavities; there is a temperature range of about 130 degrees F.

With hot air blowers the air is circulated through a bag at a temperature not to exceed 130 F. When these blowers have been directed against the bare skin, burns have occurred.

A new device for a hot water bottle consists of an electrical metal heater which protrudes down into the water, so controlled that the water is kept at a constant temperature. In order to avoid burns, this should not be set for more than 125 F.

The automatic electric blanket is a blanket thermostatically controlled wherein the temperature is maintained at a constant level despite environmental changes.

Cooley compresses, Council accepted, keep a constant warmth in wet dressings by means of a waterproof electric pad.

Brown and Allen have described electrical cuffs and sleeves, controlled by accurate thermal regulating mechanisms; but this apparatus is still in an experimental stage of development.

Chemical heat is to be had in the form of eye pads and sinus pads. A uniform heat of about 108 F. to 114 F. is maintained for about an hour. Chemical crystals within these pads, when moist, give off heat as the result of chemical reaction.

These Council accepted devices, when in good working order, are safe and convenient means by which dry or moist heat may be applied; if they were used more frequently by physicians and hospitals better clinical results would be obtained without the hazard of burns. Burns may vary from a devitalization to complete destruction of the tissues involved. They may occur immediately or take place in several minutes, hours or even days after the original exposure. The degree of tissue destruction may vary from an erythema of first degree with blistering of the superficial layers of skin to coagulation and destruction of the deeper structures. These wounds become easily infected. They are indolent

in healing and often result in unsightly scars. Following infra-red exposure, a mottling of dark red spots over the area treated means that there has been too much absorption of heat, and it will be followed by edema of the tissue and finally by blistering. When any such accident as this occurs, legal advice should be sought immediately.

To date there is no better means of estimating the amount of heat to be given by means of short wave diathermy than the sensation of the patient; therefore, the degree of heat must be limited to that which produces no unpleasant sensation or pain. As symptoms of overheating there are pain, aching, soreness, weakness, edema and effusion. The limit of tolerance in inflammatory tissue is always lower than that of normal tissue. Here, again, it will be well to stress the need of knowing that the nervous and circulatory systems are intact. In treatments about the head, dizziness or giddiness is an indication for discontinuing the treatment. In heart disease, the occurrence of tachycardia would mean that treatment should be stopped. Contraindications must be carefully studied and heeded; after treatment has been instituted any untoward signs must be noted. To keep out of trouble, such danger warnings must not be ignored.

Knives, keys, money, watches and other metallic substances should be kept out of the field of operation. Tables and chairs should have no metal parts. Beds equipped with wire or innerspring mattresses are a fire hazard.

When diathermy is prescribed for use in the home, the physician must remember that he is liable for accidents or bad results attendant on its use. To protect himself, therefore, he should see to it that the apparatus secured for such treatment is Council approved, that it is in good working order and that its operation is understood by the person who is to administer the treatment. In order more thoroughly to protect himself, he should have a trained technician go to the house to administer the treatment prescribed and to watch over the patient during the course of the treatment.

Fever therapy requires specialists in that field for its administration. Its value is well known, and soon it will become important from a medicolegal standpoint.

Ultraviolet therapy ranks near the top of the list as one of the causes for medicolegal action. It should, as a matter of fact, be one of the safest of energies. When burns have occurred it has been found that there is far less permanent tissue destruction than results from the use of other energies. In order to safeguard oneself when using ultraviolet therapy, individual lamps should be standardized, since they vary in erythema potency. Rooms in which treatments are given should have adequate ventilation. Goggles or a shield should be used over the eyes of the patient. The genitalia should be covered; the breasts of women also should be protected. Hypersensitivity and the patient's individual reaction to ultraviolet therapy must be studied; as an example, senile and keratotic skins may predispose to the development of cancer. Minute attention must be paid to the dose that the patient can take safely. This individual limit of safety must be determined before the patient is subjected to treatment, and subsequent treatments must be governed according to the observations made. Diabetic patients often react unfavorably to irradiation, with resulting local and general petechial hemorrhages, but it is also a form of treatment which has been shown

to be of real value in reducing blood sugar levels. One of the really important considerations is provision for the sounding of a time clock to measure the length of exposure.

From a medicolegal standpoint, if an energy is to be used the physician should know that it has been used and been proved an advantage by other authorities. Some of the absolute and proved indications listed by the Council on Physical Therapy of the American Medical Association for the use of ultraviolet radiation are for prophylactic and curative effects in rickets, infantile tetany, spasmophilia and osteomalacia. Other relative indications may be found in anemia, hemophilia, chlorosis, tuberculosis and arthritis. The user of these energies will do well to prescribe them when indicated, but I should like to repeat that he must have full knowledge of the various forms and technics of application, must be well aware of the hazards involved and must be wary with regard to experimentation; otherwise he may find himself with legal problems to settle.

MANIPULATION OF DEFORMED JOINTS

Manipulation of deformed joints is a form of physical therapy which is often followed by legal action. A mechanical apparatus for manipulative procedures on arthritic or deformed joints is packed full of dynamite. More than ordinary care should be practiced. The danger of producing fractures of atrophied bones is ever present, and permanent ankylosis sometimes results. Before operations of this nature are undertaken it would be wise for the physician to secure data which might seem entirely too detailed—measurements alone are not sufficient—actual photographs should be taken to substantiate the measurements, and any significant observations recorded. A defendant coming before a court, council and jury who has not a complete record of the conditions when he started treatment has little argument to offer in his own defense and has as good as lost the case before entering court.

One might think that there is little trouble to result from treatment by massage. Even in this there are certain precautions to be observed. One must not allow the patient to be exposed to a chill when heat has been applied. When the area to be massaged is covered with hair the part should be shaved, or particular care should be used to avoid irritation which might result in a folliculitis or pustular infection, with indolent response to treatment. Massage varies enough in type so that here again a definite prescription should be written, calling for a stroking, kneading, percussion or vibratory method. Massage, too, has its contraindications. These are found in tumefactions in which there may be a malignant condition, in dermatoses, in inflammatory conditions such as swollen and painful joints and in cases of systemic disease with fever. There are many contraindications which, if not heeded, could easily lay grounds for legal action.

HYDROTHERAPY

Hydrotherapy is another form of physical therapy which may be so simple as to call only for early morning hikes barefooted through dew-covered grasses and on the return from such a jaunt drinking as much water as one can hold. Baruch described hydrotherapy as the application of water in any form, from solid and fluid to vapor, from ice to steam, internally and externally. In its place, one may expect good results.

from treatment of this kind; but one must not be so optimistic as to disregard dangers which may be encountered.

PARAFFIN BATH

The paraffin bath is designed to facilitate and simplify the application of heat over the joints and other affected parts of the extremities. The temperature of the melted paraffin should range from 120 to 130 F., and 20 per cent should be liquid petrolatum, that is, 4 parts paraffin and 1 part liquid petrolatum. Implicit instructions should be given patients with regard to preparing this in the home to use a double boiler when melting the paraffin and to turn out the fire under the container before the mixture is applied. The patient who does not foresee the possibility of burns must be forewarned. A bath thermometer may be used to determine the temperature. For those who have no thermometer it is safe to use the mixture after it has cooled to a point at which a slight scum forms over the surface. The fingers should be held apart when the hand is immersed; after the paraffin has started to set, the part dipped should be held quiet to avoid cracking of the paraffin, for when this happens subsequent immersion may cause burns. It is important to time these treatments. They are to last, as a rule, from fifteen to forty-five minutes. Mixtures of paraffin and oil may be used repeatedly without changing, since the material sterilizes itself. Hair over any of the parts treated should be shaved.

There are special apparatuses¹ on the market for the paraffin bath, constructed with special heating elements, and with positively regulated controls for temperature and time limit.

GALVANIC CURRENT

Galvanic current of but a few milliamperes may cause tissue destruction if concentrated on a small area. Galvanic current is used to drive certain metals or drugs into the tissues for their superficial penetration and later absorption by the blood stream. While the penetration of these ions is slight, there is danger of producing a tattoo if the current is introduced from the positive pole through a steel needle. The physician who attempts epilation is laying himself open for possible court action.

COLONIC THERAPY

Much may be said of the dangers which may arise from the use of colonic therapy. The uses and abuses of this form of treatment are many; yet in trained hands and with the proper technic it is a valuable adjunct to the treatment of some diseases. All that is required by way of pressure is $\frac{1}{2}$ pound, which is the equivalent of 1 pound of water held 13 $\frac{1}{2}$ inches high. A douche held 4 $\frac{1}{2}$ feet high will give a pressure four times greater than is needed, and the pressure is increased 1 pound for every 27 inches that the container is raised. Because of the likelihood of rupture of diverticula, one can readily understand the importance of having a given elevation and a controlled pressure.

Stiff colon tubes have been known to rupture thin-walled diverticula. The so-called high enema has been a great talking point with irregulars and with some of the regular profession. It has been found that the tube seldom reaches farther than the splenic flexure, and most often it curls up before reaching that point. It so happens that the normal gradient for fluids is from the rectum to the cecum; therefore, nothing is to be gained by trying to insert a tube any depth beyond the rectum.

1. These may be obtained from the Thermo-Electric Company, 717 Frankfort Avenue, Cleveland.

The major contraindications in colonic therapy are severe cardiac disease, aneurysm, advanced arteriosclerosis, severe anemia, high fevers, exophthalmic goiter, gastrointestinal ulcer (hemorrhage or perforation), great debility from any cause, and anal disease (such as severe hemorrhoids, pruritus, eczema or stricture).

CONSULTATION

It is a wise man who will call for consultation when a course of treatment is not clear. It is well to invite other opinion as a check on one's own judgment. As said before, the law requires that a physician bestow such reasonable ordinary care, skill and diligence as is prevalent among physicians and surgeons in the same general line of practice. To seek consultation is to use reasonable and ordinary care and may be considered a precautionary measure.

INSURANCE

Every physician using physical agents should be well covered with a standard policy in an A 1 company. He may seek the advice of his local county medical society as to which insurance carrier is the most reliable and offers the best coverage. Generally the premium varies according to the apparatus used. Many companies do not offer liability coverage for those using physical therapy equipment. It has been said that during the five year period that ended Dec. 31, 1940 there were approximately 1,214,200 claims filed by security workers of the Work Projects Administration and about 201,000 claims filed by civil employees of regular government establishments. Apart from roentgen and orthopedic practice, physical therapy stands at the head of the list for the number of damage suits, also for the number of judgments rendered the plaintiff. This report has not been reviewed by the U. S. Employees Compensation Commission, and any statement or expression of opinion contained herein is my own and does not necessarily reflect the point of view of the commission. These numbers do give some idea of the fact that people are what might be called claim minded and that it behooves the physician to be well protected.

BILLING THE PATIENT

In the face of unfavorable results which might lead to legal action careful judgment should be used with regard to the total charge. It may be wise not to bill immediately, it being remembered that time is often a great mental and physical healer; however, a bill should be sent. Only under special conditions should the physician fail to send his bill; but to cancel the bill entirely might easily be assumed as evidence of guilt or neglect on his part. One statement should be sent, the fact being noted on the ledger. The receipt of such a bill will arouse a response on the part of the patient, and the physician will then be in a position to judge the attitude of the patient. He may have occasion to consult his insurance carriers without delay.

CONCLUSIONS

When physical therapy apparatus is used it should be Council approved.

The physician's assistants should be well trained, registered technicians.

The physician assumes a medicolegal responsibility when he prescribes any form of physical therapy. His instructions should be explicit and preferably in writing.

Consultation is reassuring and is valuable as a safeguard.

Medicolegal entanglements would be reduced to a minimum if members of the profession would exercise every precaution and practice only the well established and safe methods.

CYCLOPROPANE ANESTHESIA AT THE ROCHESTER GENERAL HOSPITAL

REVIEW OF 7,120 CASES

S LEROY SAHLER, M.D.

JOHN F. KELLOGG, M.D.

AND

RICHARD B. PHILLIPS, M.D.

ROCHESTER, N. Y.

It has now been twelve years since Lucas and Henderson¹ of Toronto introduced cyclopropane to the medical profession and seven years since the first clinical report by Stiles, Neff, Rovenstine and Waters.² In 1939 the Council on Pharmacy and Chemistry of the American Medical Association reviewed the work that had been done up to that time with cyclopropane in anesthesia and concluded that this agent was of value in the hands of competent anesthetists. The Council suggested, however, that more reports of anesthetics carried out with cyclopropane would be necessary before the proper place which cyclopropane might have in anesthesia could be accurately determined. Our purpose in this paper is to present a review of 7,120 cases in which cyclopropane has been used at the Rochester Hospital during the years 1935-1940 inclusive.

Table 1 shows the rate of increase in the use of cyclopropane at our hospital, by years. In the first year that we used this agent, 1935, the number of cases was 107; last year (1940) the number was 1,639. During the past two years cyclopropane has been used in nearly half of all our inhalation anesthesia, as may be seen in table 2. In 1939 42 per cent of all gas anesthesia was with cyclopropane, and in 1940 45.5 per cent of all inhalation anesthesia was done with this agent. This year the figure will probably be greater than 50 per cent. These figures compare nicely with Hathaway's³ statistics, from Waters' clinic, who stated that "slightly less than half of 4,668 anesthetic administrations at the Wisconsin General Hospital in 1938 were done with cyclopropane." Guedel⁴ has recently reported the results of more than 8,000 cases conducted by himself and by Treweek and McCuskey. These men believe that cyclopropane is as safe as any other anesthetic in the hands of trained men. Guedel emphasizes the fact that one must study cyclopropane anesthesia assiduously if one hopes to master the technique of administering it safely. Griffith⁵ of Montreal has just published his results in 5,000 cyclopropane anes-

thesias. He now uses this gas in more than 90 per cent of all inhalation anesthesia. Of his large series he felt that not more than three postoperative deaths could in any way be attributed to cyclopropane, and there were no immediate deaths. Like Guedel, he obtains full abdominal relaxation with cyclopropane alone, and he has used this gas in 586 upper abdominal cases alone without either or abdominal block.

Bogan⁶ in 1939 reviewed 1,000 consecutive anesthetics which he had conducted and found that he had used cyclopropane in 643 instances.

Before describing our own results with cyclopropane we will consider a few recent papers on various aspects of anesthesia conducted with this gas. Among the assets which may be attributed to cyclopropane are the following: 1. The induction period is comparatively fast and pleasant. 2. It may be given with a high concentration of oxygen. 3. The depth of respiratory excursion may be controlled, thus making the gas an ideal anesthetic for lung surgery. 4. Under full anesthesia there is quiet breathing and complete relaxation. As liabilities may be listed: 1. It is explosive in anesthetic concentration. 2. There is somewhat more bleeding under this anesthetic than under most others. 3. There is danger of respiratory paralysis when complete relaxation is obtained. 4. The patient passes from plane to plane of anesthesia faster than with almost any other agent.

Many hospitals throughout the country are not using cyclopropane because of its explosiveness. It is true, of course, that there have been several unfortunate instances in which this gas has exploded, and deaths have resulted. Horton⁷ of the Massachusetts Institute of Technology, who has been investigating this subject in great detail, says that statistics are inadequate to show whether any one gas used in anesthesia is more

explosive than the others. He points out the importance of flooring, shoes, wiring, electric switches, intercoupling, clothing, electrostatics, humidity, furniture, pads, pillows and the anesthesia machine itself in the cause and prevention of anesthetic explosions. On the other hand, as pointed out by Jones, Kennedy and Thomas,⁸ of the United States Bureau of Mines, the

explosibility of cyclopropane in anesthetic concentration may be considerably diminished by the addition to it of nitrous oxide, air, helium and carbon dioxide. Jones and Thomas⁹ now advocate the administration of a cyclopropane-helium-oxygen mixture in the ratio of 25-50-25 as being of definite value in preventing explosions. Greene,¹⁰ who recently reviewed 230 cases of anesthetic explosions for the American Society of

Avertin with amylene hydrate was used as a basal anesthetic in 111 cases, of which 92 were toxic thyroid cases. Endotracheal intubation was performed in 71 instances. In addition to the 734 appendectomies there were 141 appendices removed incidental to cholecystectomy, oophorectomy, hysterectomy and other operations.

Anesthetists, finds that 40 per cent of these accidents occurred in the presence of electrical machines such as diathermy apparatus and endoscopic, x-ray or cautery instruments. Another 59 cases (25.6 per cent), he says, could be attributed to suction apparatus. This means then that 65 per cent of all these explosions might have been prevented, and it must be remembered that the explosions just referred to involved all types of gas anesthesia, not just cyclopropane alone. Greene was able to find no case in which cyclopropane-air exploded, a fact which may have some significance. We in Rochester feel fortunate with regard to our relative humidity, as our position on Lake Ontario gives us a relatively high humidity, a fact which tends to prevent static electricity explosions. It is interesting to know that there has never been a static explosion in Australia and only one in England, facts which speak for themselves. Greene states that in the series which he studied the relative humidity in sixty-three static explosions was lower than 50 per cent in 32 cases. His conclusions are that there is no single effective way in which to prevent explosions but that a combination of factors must be considered, beginning first with the intelligence of the person administering the gas. Explosions have occurred under every known method of protection but frequently in the presence of apparatus which should have been excluded from the operating room or owing to faulty technic in administering the gas.

The question of excessive bleeding in the surgical field has been the subject of investigation. Some surgeons seem to be definitely against the use of cyclopropane on this account; others pay little or no attention to it. Waters¹¹ has shown that cyclopropane does cause oxygen saturation of the venous blood which will equal arterial blood. Associated with this there is an

increase in capillary bleedings which is believed to be due to compensatory sympathicotonia and hyperadrenia. Abramson, Grollman and Schwartz,¹² using the plethysmographic method, have found that there is an increase in blood flow through the hand and forearm during cyclopropane anesthesia. This work confirms the known observation that cyclopropane does diminish vasomotor tone. Whether or not this decrease in arteriolar tone is sufficient to interfere with surgery is a matter for the individual surgeon to decide. Our own surgeons feel that the advantages in using cyclopropane greatly outweigh the slight to moderate excess oozing which frequently does occur. We must remind ourselves of the work of Mann,¹³ however, who has shown that even with ether there is an increase in the blood flow of 64 per cent in the peripheral arteries, under light anesthesia. Guedel⁴ speaks of the "arteriolar-capillary-refill time" or the "A-C-R" sign, which he believes is of special value in determining circulatory efficiency under cyclopropane anesthesia. The A-C-R refers to the refilling of the capillary bed when pressure is exerted on the skin of the forehead, and it remains the same regardless of the depth of the anesthesia. It slows perceptibly, however, in the presence of shock or loss of blood. Guedel states that, if the A-C-R is satisfactory even in the presence of an arrhythmia, poor pulse or apnea, the patient is not in immediate danger.

We have used cyclopropane in almost every type of surgery, as may be seen by referring to table 3. Of the 3,103 cyclopropane cases during 1939-1940 abdominal surgery was done in just exactly 50 per cent. It has been necessary to supplement cyclopropane with ether in 6 per cent of the cases of abdominal surgery, although frequently but small amounts of ether were used. We have found that, in the great majority of cases in which we have used cyclopropane in abdominal surgery, relaxation can be obtained and maintained with cyclopropane alone. We agree with Guedel⁴ that it is possible to obtain relaxation with cyclopropane comparable to that obtained with spinal anesthesia. This almost always means, however, that apnea will supervene and that for at least part of the anesthesia it will be necessary for the anesthetist to control the patient's respirations passively. As is well known, apnea may occur at any time during cyclopropane anesthesia, during induction or at any later phase. Passive respiration can be kept up by the anesthetist for some considerable time when necessary, even for three quarters of an hour or longer. When active respiration reappears it must be amplified in most cases, as pointed out by Greeley,¹⁴ by passive respiration in order to insure adequate pulmonary ventilation. Inadequate active ventilation and respiration is much more dangerous than passive respiration with its hyperventilation. One must pay special attention to the excretion of cyclopropane. The high oil-water solubility ratio permits the cyclopropane to be absorbed by the body fats readily, and, since the gas must first pass through the blood plasma in reaching the fats and then back through the plasma in being excreted, it follows that there is built up in the fats a high proportion of cyclopropane which must

9. Jones, G. W.; Kennedy, R. E., and Thomas, G. J. Explosive Properties of Cyclopropane. The Prevention of Explosions by Dilution with Inert Gases. Report of Investigations, R. I. 3511, United States Department of the Interior, Bureau of Mines, 1940.

14. Greeley, Paul, cited by Guedel⁴.

not be overlooked. In the latter part of anesthesia this factor is not so important, as a leveling off process takes place following the decreased amounts of cyclopropane given after full anesthesia has taken place. When active respiration returns, one may even assist it by adding small amounts of carbon dioxide to the already diluted gas. Some anesthetists recommend the use of carbon dioxide routinely after operation, but we do not use it unless we feel that there is some special indication for it.

One of us¹⁵ has recently reported from this hospital the administration of cyclopropane in 94 cesarean sections. To these 94 cases we now add 44 done under cyclopropane during 1939 and 1940, making a total of 138. We have found that cyclopropane is of special merit in cesarean section. The patients do not perspire as they used to, the babies seldom have to be resuscitated, and it is possible to flush oxygen through the mother's blood and into the baby just before the cord is cut. We have had only 4 deaths in 423 cesarean sections in the last twelve years, and none under cyclopropane. One death was due to embolus on the thirteenth postoperative day.

It is of the utmost importance that the patient be provided with a good airway during cyclopropane anesthesia. Relaxation of the tongue and shallow chest excursions make it imperative that the patient receive adequate amounts of oxygen. Our custom is to introduce an ordinary flat pharyngeal airway in every case as soon as anesthetization has been obtained, which is usually from four to seven minutes after the beginning of induction. Griffith⁹ used endotracheal intubation in 1,567 of his 5,000 cases, or nearly 1 case out of every 3. In our last 3,103 cases we used the endotracheal technic in 71 instances. However, we use the method a good deal more than this figure would indicate, as we are not counting our nitrous oxide and ether cases in this series. We are using the intratracheal tubes more and more, but up to the present we reserve intubation for the more difficult cases, and we insert the tubes usually in the beginning, after induction, rather than after surgery has begun. We use the tubes in all lung surgery, and in work around the throat, neck and mouth.

It has been found that cyclopropane combined with basal avertin with amylene hydrate makes an excellent combination anesthesia for toxic thyroid surgery. We used this technic in 92 cases with excellent results. Avertin with amylene hydrate was used in a further 19 cases in combination with cyclopropane when it was considered wise to bring the patient to the operating room under basal anesthesia. It has been found that cyclopropane is very useful as an adjunct to spinal anesthesia. When a patient receiving spinal anesthesia is too alert and nervous or when the spinal agent is beginning to wear off, one may give comparatively small amounts of cyclopropane and at the same time keep up the concentration of oxygen which is so desirable in spinal anesthesia.

We agree thoroughly with Griffith, Guedel and Waters and Schmidt¹⁶ that cyclopropane is the anesthetic of choice in poor cardiac risks. We have also found that Hathaway's figures on respiratory morbidity are well founded. He states that following cyclopropane, ether and nitrous oxide anesthesia the percentage morbidity in chest complications is 1.08, 2.06 and 2.17.

At the Rochester General Hospital we use the carbon dioxide absorption technic in nearly every case. However, there are times in cyclopropane anesthesia when one wants to let the patient have his own carbon dioxide or to supply him with some. The use of the carbon dioxide absorption technic with the closed system allows us to save cyclopropane, which is, as is well known, an expensive gas. After anesthesia has been obtained one may use as little as 40 to 150 cc. a minute to maintain anesthesia, with occasional supplements of larger amounts at intervals, depending on circumstances. A basal flow of oxygen of from 250 to 500 cc. a minute is constantly maintained. We believe that it is possible to give as many anesthetics with 10 dollars' worth of cyclopropane as it is with 10 dollars' worth of nitrous oxide.

Preoperatively we use morphine, scopolamine, soluble pentobarbital, seconal (sodium propylmethylallylbarbiturate) and combinations of these drugs, as we found out long ago that a much smoother anesthesia is obtained if the patient comes to the operating room under proper medication. Induction is easier, and the deep relaxation necessary for certain abdominal surgery is obtained with greater security. Robbins¹⁷ has considered premedication in detail, and he has shown that if barbiturates are given preoperatively there is less tendency toward the development of arrhythmia. Cyclopropane does not abolish muscular tone when given to a depth necessary to establish complete relaxation, as does ether. For a detailed account of the administration of cyclopropane under various circumstances we refer the reader to Guedel's paper.

As stated previously, we introduce an airway in every case as soon as anesthesia has been induced. We have found that helium is often of considerable help in carrying the cyclopropane and oxygen through a compressed trachea or other obstruction to the airway. We also use helium occasionally toward the end of an operation, particularly a longer one.

Fortunately, in cyclopropane anesthesia respiratory arrest comes on before cardiac failure. This must be treated by passive respiration until active breathing returns. We feel that as long as the pulse remains over 50 the patient is not in immediate danger, but with slowing of the pulse we advance the oxygen intake. According to Allen, Stutzman and Meek,¹⁸ cyclopropane renders the heart sensitive to epinephrine. The result is that small amounts of epinephrine which are liberated during the excitement of coming to the operating room, and which ordinarily do not have any particular effect, act and produce arrhythmias. Extrasystoles are not at all unusual in this type of anesthesia, but they are not cause for alarm if respirations are even, if the pulse is over 50, and if the A-C-R reacts properly. It is well known now that one must not give drugs preoperatively that increase sympathetic tonus.

We find that cyclopropane is well tolerated by all age groups and we have no hesitation in using it with very old patients.

Finally, a few words about "cyclo shock." We have noticed many times now that a patient who has had what might be called moderate surgery with an average amount of cyclopropane will sometimes go into collapse thirty minutes to three hours after being taken back

to his room. This collapse can always be prevented or at least alleviated in large measure by the exhibition of intravenous dextrose immediately on returning to the patient's room. We use intravenous fluids in good measure in all cases of cyclopropane anesthesia of any duration and when the surgery has been of any magnitude. Since employing these prophylactic measures we have found fewer cases of "cyclo shock."

POINTS TO BE CONSIDERED

The following points are, in our opinion, the more important ones to be considered in cyclopropane anesthesia:

1. Maintain an open airway. Use a pharyngeal tube in all cases, and an endotracheal tube when the occasion warrants it.

2. Always be on the alert for apnea, and, when it arises, maintain passive respiration until active respiration reappears.

3. In induction, adjust the mask tightly before opening the cyclopropane valve. Fill the bag half full of oxygen, and after the patient has had a few breaths introduce cyclopropane at the rate of 600 to 700 cc. a minute. After anesthesia has been established, cut down the cyclopropane flow to 40 to 150 cc. a minute but keep the oxygen flow at 250 to 500 cc. a minute. Introduce larger amounts of cyclopropane, depending on relaxation and breathing. A good level of anesthesia will be reached when the muscles of the face and neck are relaxed, when breathing is slow and rather shallow and when the abdominal muscles are soft, as reported to the anesthetist by the surgeon.

4. Do not administer sympathetotonic drugs preoperatively.

5. Give adequate preoperative medication.

6. Do not use any more cyclopropane than is necessary; the larger the amount used, the greater will be the degree of "cyclo shock."

7. Be on the watch for "cyclo shock" during the first half hour to four hours postoperatively and administer adequate amounts of acacia, dextrose and saline solution to all patients who have had cyclopropane in major surgery which has lasted longer than the average time for the given procedure.

8. When the operation has been of considerable duration, always use carbon dioxide inhalation intermittently for from twenty-four to forty-eight hours.

9. Use the carbon dioxide absorption technic in giving cyclopropane routinely but not exclusively. Carbon dioxide is useful during cyclopropane anesthesia at times.

10. Helium is useful as a carrier of cyclopropane and oxygen through a partially obstructed airway. It is also of value in decreasing the explosibility of the cyclopropane-oxygen mixture.

11. Have suction available, conducted through the wall of the operating room and not obtained by means of a suction machine close at hand.

12. Remember, a pulse rate below 50 indicates that the patient has had sufficient cyclopropane; it does not mean that the patient is in a dangerous position, but oxygen should be given at once in full concentration.

13. Ascertain in every case before operation whether the cautery or x-ray or endoscopic apparatus is to be used; if so, use another gas if inhalation anesthesia is required.

14. There has been no mortality in the 7,120 cases, but there has been an influence by cyclopropane on morbidity, we feel sure. We do not feel that a single case of death has been due to cyclopropane alone.

15. There is no hard and fast rule in the conduct of cyclopropane anesthesia. Each case must be handled individually and as an entity in itself. With reasonable experience the technic of cyclopropane anesthesia is not difficult; but it does require assiduous attention to the various points enumerated.

Medical Arts Building.

THE CONTRACEPTIVE SERVICE OF THE DEPARTMENT OF HEALTH, CITY OF NASHVILLE

GILBERT W. BEEBE

NEW YORK

AND

JOHN OVERTON, M.D.

NASHVILLE, TENN.

In November 1937 the health department of the city of Nashville opened a contraceptive clinic for indigent women. Health and economic conditions among the underprivileged of Nashville accentuated the need for lessening the high frequency of conception in this group. Appreciation of the difficulties of prescribing diaphragm and jelly for indigent multiparas led to the decision to provide a substitute method for women difficult to fit or otherwise unable to employ the diaphragm. Foam powder was chosen for its apparent simplicity, its low cost and its reported effectiveness in early trials elsewhere. Although the physician in charge of the clinic exercised no rigorous selection of cases, he did tend to prescribe foam powder for the apparently less intelligent and for patients having a relaxed pelvic floor or presenting other conditions prejudicial to successful fitting, insertion or retention of the diaphragm in situ.

The first clinic admitted only white patients, but two clinics for Negroes were opened in 1940. Under a policy of expansion and decentralization the original clinic was closed in April 1940, after having admitted 733 patients, of whom 6 were referred for sterilization. The active cases among them were distributed to the decentralized clinics, of which there were four on June 1, 1941. Prior to this date 1,607 white and Negro patients had been given contraceptive advice.

A sample of the histories was examined in 1938 by the National Committee on Maternal Health with the expectation that the pioneer service might furnish data of considerable importance for clinical contraception. The service appeared exceptional in its provision of two methods, its integration with other public health services and its exceptionally intensive follow-up by public health nurses. The present report summarizes the experience of the original clinic and reaches some conclusions about the relative usefulness of the two methods prescribed.¹ The latter takes on special interest in the face of the current effort by birth control enthusiasts to encourage widespread use of foam powder.

THE PATIENTS

Contraceptive services are seldom, if ever, patterned along the lines of biologic experiments, with an "untreated" sample for control, and it has become customary to evaluate their influence by contrasting the

From The National Committee on Maternal Health, 2 East 103d Street, New York, and the Department of Health, City of Nashville, Tenn.

1. It should be borne in mind that the service was not planned to test the two methods for the particular set of patients. Consequently, from the standpoint of experimental control the data present shortcomings which are of little or no relevance to the efficiency of the service *qua* service.

fertility of patients before and after admission. In this study the histories prior to admission must be examined intensively not only to facilitate comparison with the later period but also in order to explore the comparability of the two groups advised in the use of different methods.

TABLE 1.—*Characteristics of Patients Given Contraceptive Advice, by Method Prescribed*

Characteristic	Method Prescribed		Total
	Diaphragm and Jelly	Foam Powder

Fertility index‡	0.41	0.41	0.41
Percentage with contraceptive experience	65	65	65

* Values in boldface are significantly different in the statistical sense

† In years of schooling

‡ Births per year of married life

A summary of the main features of these histories is given in table 1 separately for each method group. Horizontal pairs of values in boldface may be regarded as significantly different in the statistical sense.² Five of the differences merely reflect the fact that the foam powder patients were, on the average, two or three years older than those advised to use diaphragm and jelly. The differences in duration of marriage, gravidity, parity and family size repeat the age difference. The important point is that relative fertility, as measured by births per year of marriage, is the same for the two groups. Patients who had experienced pregnancy and childbirth more than the average number of times more frequently presented apparent contraindications to the diaphragm prescription and thus entered the foam powder group in greater numbers. The possible implications of this selection are manifold, but they furnish no reason for regarding the two groups as essentially different in inherent fecundity or in the desire and ability to control conception.

The superior education of the diaphragm and jelly patients is also consistent with the process of selection but difficult to evaluate. There is a difference of seventenths grade between the two means, and the diaphragm and jelly cases include a third with more than eight years of schooling in comparison with a fifth of the foam powder patients. While the difference between means is not large, the proportions entering high school suggest that the two groups may differ in motivation, intelligence and other characteristics associated with contraceptive efficiency. On the other hand, the homogeneity of the two groups with respect to relative fertility and resort to contraception is inconsistent with the assumption of effective differences in contraceptive interest and skill. The educational differential seems an insufficient basis for regarding the two groups as incomparable.

2 A difference is called statistically significant here when it is of a magnitude which might be expected to arise by chance five times or less in a hundred trials ($P \leq 0.05$). In the absence of a contrary statement, any difference or other relationship given in the text has been subjected to a statistical test believed appropriate and has been found to be reliable in this sense.

Although the two groups are not entirely homogeneous, therefore, the statistical analysis suggests no reason why there should be any appreciable differences in fertility under similar circumstances. To the extent that this interpretation is justified, the subsequent experience of the two method groups provides a direct test of the relative suitability of the two methods for the type of patient admitted to the service. Since their comparability is not firmly established,³ conclusions must be regarded as tentative.

The relative fertility of several other groups of contraceptive patients with little previous contraceptive experience is given in table 2 by residence and color. The Nashville rate of 0.41 is well within the range of 0.40 to 0.47 obtained for samples drawn from areas of extremely high fertility. A majority of the patients avowed at least some effort to control conception, the proportions, however, being above average for those favored by superior education, income and employment status. The fertility rates of table 2 show how little their previous contraceptive endeavors had lowered the fertility of these patients before admission to the service.

ACCEPTANCE OF PRESCRIBED METHODS

Only 5 per cent of the patients failed to try either diaphragm and jelly⁴ or foam powder and sponge⁵ as prescribed, and the difference between the two groups is insignificant. Immediately thereafter, however, the foam powder patients displayed less willingness to employ the prescribed method, as may be seen in the accompanying chart. This shows, for example, that after six months of exposure (perhaps eight or nine months after admission) less than 55 per cent of the foam powder patients were still using the prescription in comparison with more than 75 per cent of the diaphragm and jelly patients. At the end of twelve months of exposure the percentages had fallen to about 35 and 60. The great discrepancy between the two curves is partly illuminated by the reasons for discontinuance, shown in table 3. One important factor is reported as

TABLE 2.—*Comparative Fertility of Patients of Little Contraceptive Experience Prior to Admission to Several Contraceptive Services, by Residence and Color*

Residence, Series and Color	Births per Year of Married Life

"burning." Ten per cent of the foam powder patients and 1 per cent of the diaphragm and jelly patients stopped because of "burning." Another outstanding

3 As it would be under appropriate conditions of random selection of patients for the two methods.

4 The following commercial jellies and creams were prescribed in the clinic: Cooper Creme, Holland Rantos Emulsion Jelly, Koromex Jelly, Lactinol Creme, Lactinol B and Ramses Jelly.

5 P. S. Foam Powder was advised. The manufacturer, Philip Stoughton of New York City, gives the quantitative formula, on the basis of weight, as cornstarch 84.25 per cent, Duponol W. A. 14 per cent and paraformaldehyde 1.75 per cent. Duponol W. A. is a commercial detergent obtained by sulfonating technical lauryl alcohol.

difference in the table centers on the combination of lack of confidence, preference for another method, and change of prescription,⁶ for which the relative losses are 18 and 7 per cent. The third major source of variation is the relative frequency of conception during use of the prescription. The percentages of 16 and 8 suggest that foam powder may have provided materially less protection than diaphragm and jelly. Each of these three differences is statistically reliable and, taken together, they explain most of the divergence in the curves shown. Noteworthy for both groups are the low percentages of cessation associated with apathy, moral or religious objection, belief in protection from lactation or some pathologic condition, and esthetic objections.

The two method groups differ appreciably in their dependence on the prescribed methods after admission to the service. Table 4 gives the percentages of patients reporting several types of contraceptive experience and shows that more patients relied exclusively on dia-

Decline in percentage using prescribed methods

phragm and jelly than on foam powder. Measured as a percentage of all exposure after admission, the relative dependence on diaphragm and jelly was 78 per cent and on foam powder 64 per cent. The slightly greater resort to other methods of contraception on the part of the foam powder patients is not statistically reliable. The two groups substituted essentially the same methods for that advised, withdrawal and condom being most frequent and douche rather infrequent. It will also be noted from table 4 that the two groups differ only insignificantly in their failure to take contraceptive precautions at any time after admission. If the foam powder patients more frequently experienced conception, of course, they would be expected to refrain from contraception more often simply because of postpartum amenorrhea and lactation. The two groups do differ significantly, however, in the extent to which the initial prescription was subsequently changed. Two per cent of the diaphragm and jelly patients and 15 per cent of the foam powder patients were given other methods.

Whatever index of acceptance after trial is employed, therefore, the foam powder method appears to have been definitely less suitable for the patients advised in its use than is true of the diaphragm and jelly method. While the interpretation of this finding is obscured

by the selection of the patients, at several important points the hypothesis of homogeneity of the method groups as to basic contraceptive motivation and ability withstands statistical test. If the two groups differ widely in these respects, they should also differ in resort to other methods of contraception and in failure

TABLE 3—Percentage of Patients Abandoning Prescription for Stated Reasons, by Method Prescribed

Reason	Method Prescribed		Total

* Less than 0.5 per cent

to adopt precautions. Table 4 gives no support to this view. Moreover, the fact that many more of the foam powder than of the diaphragm and jelly patients petitioned for a different prescription does not accord with the view that the former were less highly motivated. Finally, the two method groups are homogeneous with respect to the proportion who, after abandoning the prescription, failed to take up any other method within the period of follow-up. Thus the analysis of the contraceptive experience after, as well as before, admission to the service gives no reason to abandon the position⁷ that a comparison of the experience of the two groups throws light on the relative utility of the two methods for the type of patient admitted to this service.

EFFECTIVENESS OF PRESCRIBED METHODS

In formal analysis it is useful to make a distinction between the acceptance of a prescription and the protection obtained from its use, but the two elements are clinically inseparable. This is illustrated by the asso-

TABLE 4—Percentage of Patients with Specific Contraceptive Behavior After Admission, by Method Prescribed

Contraceptive Behavior *	Method Prescribed †		Total
	Diaphragm and Jelly	Foam Powder	
All exposure with prescription	46	37	42

ciation between unwillingness to continue foam powder and lack of confidence in its effectiveness. Contraceptive effectiveness may be defined in terms of reduction in the chance of conception. If the expected risk of conception is R , and the observed risk R' , then the difference $R - R'$ measures the reduction, which may be

7 The statistically minded reader will appreciate the fact that no amount of statistical testing can prove the homogeneity of two groups of patients. Insignificance in such tests merely provides no reason to reject the hypothesis of homogeneity.

6 These interrelated elements were not separated in the coding.

stated in relative form by means of the expression $100 \times \frac{R-R'}{R}$. If the expected risk R is taken as that which would have obtained had no contraceptive been employed, then $100 \times \frac{R-R'}{R}$ may be said to measure the effectiveness of the particular contraceptive practice giving rise to the risk R' . This definition makes no statements about an invariant, physiologic "effectiveness," but refers to observable clinical experience representing, as it does, the physiologic action of the contraceptive modified by whatever competence and diligence the patients manifest. At present the physiologic and the behavioral components of risk cannot be separated clinically, and only measures of use effectiveness are possible.

To apply this procedure, essentially that of Stix and Notestein,⁸ a statistic is required for estimating the chance of conception. The best available device is the pregnancy rate invented by Pearl.⁹ In its most general form the pregnancy rate may be stated as

$$Rp = \frac{\text{number of conceptions}}{\text{number of possibilities for conception}}$$

The particular rate employed here defines as the unit of possibility for conception the exposure month, an elapsed month in the married life of a patient during

frequently endeavor to isolate the conceptions which apparently intervened despite the regular and competent use of a prescribed method, but the desired estimates of risk require that the exposure meeting these criteria also be isolated. The latter is virtually impossible in a series such as the present one. Parenthetically it may be noted that 18 per cent of the diaphragm and jelly conceptions, and 31 per cent of the foam powder conceptions, were asserted by the patients to have occurred despite their regular and competent use. In 72 per cent of such instances the history shows that the nurse did not believe the patient. The director of the nursing service maintains the view, based on her intensive study of individual cases, that neither method has yet "failed," in the physiologic sense, any patient in the series.

The measurement of effectiveness requires an estimate of the uncontrolled chance of conception. The data on gravidity, parity and duration of marriage provide the basis for an estimate of seventy-five pregnancies per hundred woman years of exposure, which checks closely with other series in which more precise estimates have been made. Table 5 gives the pregnancy rates and the relative efficiency for each method. Allowance for minor variation in the expected rate could in no way disturb the conclusion that the effectiveness of diaphragm and jelly greatly exceeded that of foam powder. On the other hand, it is evident that the 88 per cent protection obtained with diaphragm and jelly is higher than might have been anticipated from previous studies, for it approximates the protection reported for a private practice series¹¹ and for outstanding urban clinics¹² ministering to the needs of women of greater economic and social privilege. The foam powder protection of 63 per cent is also very real, and the combined effectiveness of the two methods represents definitely superior protection. One reason for the generally favorable result is believed to be the intensive care which the patients received from public health nurses, for the average diaphragm and jelly patient was seen nine and three-tenths times during fifteen and five-tenths months of follow-up and the average foam powder patient eight and one-tenth times in fifteen and three-tenths months. Without the frequent home visits and the skilful nursing made possible by incorporating the contraceptive service into the general public health program and by the exceptional interest of the director of the nursing service, far less than 80 per cent protection would probably have been achieved.

The difference in effectiveness is both large and independent of any differences between the groups with respect to education, income, prior contraceptive experience and duration of marriage. The selection of the foam powder patients for greater age, parity and gravidity should tend to yield a group slightly below average reproductive capacity,¹³ for the relative fertility of the two groups was the same before admission. The latter finding makes highly improbable the existence of any real physiologic difference, e. g. a gaping os uteri or other gynecologic condition which might diminish the occlusive power of the foam and sponge and thus prejudice the result. Moreover, the foam powder patients actually experienced an insignificantly lower

TABLE 5.—Relative Effectiveness of Prescribed Methods

Prescription	Experience with Prescription		Expected Rate * on Assumption of No Contraception (Estimated)	Percentage Effectiveness
	Exposure, in Months	Conceptions		
Diaphragm and jelly	4,336	32	9	75
Foam powder	2,470	57	28	75
Total	6,812	89	16	75

* Pregnancies per hundred woman years of exposure to the chance of conception, or $Rp = 1,200 \times (\text{conceptions/exposure months})$

which conception was physiologically possible. In other words, from the time during which the patient was under observation, deductions are made for months of gestation, puerperium, abstinence and the like, and exposure is considered to be terminated by sterilization of either partner or by the menopause. The remainder, a number of months, may be called the exposure of the particular patient. In each exposure month, conception either did or did not occur, and both conceptions and exposure months may be classified in any way justified by the character of the clinical observations. The statistical measure employed here to describe the chance of conception may thus be defined as

$$\text{Pregnancy rate} = 1,200 \times \frac{\text{number of conceptions}}{\text{number of exposure months}}$$

which gives the pregnancies per hundred woman years of exposure to the chance of conception. The rate is computed not for individuals but for groups of patients.

The clinician would like estimates of the chance of conception under conditions of perfectly regular and competent use. These would have considerable value for both research and clinical practice, but reliable observations permitting such a classification of clinical experience have yet to be obtained.¹⁰ Investigators

10. In this study, as in others under the auspices of the National Committee on Maternal Health, such estimates have been attempted but without success. For example, in coding the Nashville histories it was found that virtually all patients claimed regular use until conception occurred, after which admissions of irregularity were frequently made for experience previously alleged to have been regular.

chance of conception when they did not use the prescription than is true of the diaphragm and jelly patients. Finally, the pregnancy rates for women classified by education and income differ only insignificantly within each method group, whereas the rates for the two methods are very different for women of similar education, income and prior contraceptive experience. It is plain that the educational differential noted earlier in the paper exerts no sensible influence on the result observed. From the standpoint of both the physiologic and the psychologic determinants of protection, therefore, the evidence sustains the position that the two method groups are comparable and that their differential success may be attributed to the methods prescribed.

THE TOTAL CONTRIBUTION OF THE SERVICE

Evaluation of the total contribution of a contraceptive service must recognize that the needs for protection which patients present on admission do not vanish on their rejection of an initial prescription. Only the examination of a representative portion of their experience after admission to the service, chosen without regard for their acceptance of prescribed methods, con-

expected in the absence of any contraceptive practice is $100 \times (75 - 22) \div 75$, or 71 per cent. This is a very generous estimate of the contribution of the service, for undoubtedly some effort would have been made to control conception if the service had not been made available. The only estimate which the observations themselves provide is the rate of 40 calculated for the exposure during which the prescribed methods were not employed. In view of the high risk found for the period before enlistment it seems doubtful that a pregnancy rate as low as 40 could have been achieved without the aid of the service. Hence the use of this rate in estimating the contribution of the service is surely conservative. On this basis the gain in protection is 45 per cent for the entire series, 55 per cent for the diaphragm and jelly patients and 28 per cent for the foam powder patients.

SUMMARY AND INTERPRETATION

The observations reported here demonstrate the possibility of very extensive fertility control in Nashville among indigent white patients selected for high fertility and interest in family limitation. Despite a ready willingness to try the methods advised, however, neither

* Rates from table 5.

† Pregnancies per hundred woman years of exposure.

‡ Both rates are estimates of the risk these patients would have experienced if they had never been admitted to the service. The rate of 75 assumes that no contraception would have been practiced; the rate of 40 assumes fairly efficient and extensive practice of contraception. See text for further details.

stitutes an adequate basis for its evaluation. Completion of the present analysis, therefore, requires the presentation of the exposure and pregnancies while the prescriptions were not followed. Then the average chance of conception during the entire follow-up period may be compared with an estimate of the rate which would have obtained if the service had not been instituted.

An active service tends to drop patients unwilling to continue with prescribed methods and thus to limit its access to that part of the experience which lies beyond the control of the prescribed methods. This is also true of the Nashville service. It implies that over a longer period of observation, with a random or complete follow-up, different pregnancy rates might be obtained for the total experience and for that portion of it which does not involve the use of prescribed methods.

The supplementary data appear in table 6. The additional experience represents the use of different methods as well as some exposure during which no effort at protection was made. The rates for the two groups are 49 and 33, and for the amounts of exposure involved the difference is not statistically reliable. These rates clearly show the influence of fairly extensive efforts to control conception. The total rates of 18 and 29 summarize all the experience after enlistment for the two method groups, and the rate of 22 does this for all the patients advised. During the entire follow-up period, therefore, the total reduction below the risk

diaphragm and jelly nor foam powder and sponge proved sufficiently acceptable to prevent patients from rapidly leaving the service. The difficulty is not new; it pervades all contraceptive services organized on the basis of a single or central method, usually diaphragm and jelly. More individualized prescription¹⁴ of a wider variety of methods might make the service more effective, as would any change which reduced the likelihood of irritation or other pain and discomfort or which enhanced confidence in the technics prescribed.

Comparison of the two prescriptions presents certain hazards because foam powder was advised for patients for whom the diaphragm method was deemed unsuitable. Detailed comparison at many points, however, supports the view that the two method groups are alike in their uncontrolled pregnancy risk and in their contraceptive skill and interest. Diaphragm and jelly proved much more acceptable to patients advised in its use than did foam powder. Examination of other aspects of the contraceptive endeavor of each group furnishes no reason to believe that the apparent superiority of diaphragm and jelly is not real. The protection received from diaphragm and jelly also exceeded that obtained from foam powder by a wide margin, the effectiveness percentages being 88 and 63. Analysis of the factors influencing the chance of conception within each method group leaves little doubt that the difference is one of methods rather than one of patients.

Clinical Notes, Suggestions and New Instruments

NEAR FATAL REACTION TO TRANSFUSION WITH DRIED HUMAN PLASMA SOLUTION

S. H. POLAYES, M.D., AND J. A. SQUILLACE, M.D.
BROOKLYN

The following case is reported in support of our contention that, except in dire emergencies, cross matching tests should be performed with the patient's blood prior to each and every transfusion, whether whole blood or plasma is used.

A. N., aged 29, white, a housewife, was admitted in labor to the Prospect Heights Hospital on July 1, 1941. In her early months of pregnancy she had suffered from persistent vomiting, which, however, subsided with the usual therapy. On admission to the hospital she stated that labor had begun at 4 a. m. that day and that the membranes had ruptured two hours later. The essential observations on physical examination were as follows: The patient was in active labor with the fetus in the left occipito-anterior position. The vital signs were normal. There was a functional mitral presystolic murmur. A blood count showed the following: red blood cells 4,340,000 per cubic millimeter, hemoglobin 58 per cent, white blood cells 10,200 with 66 per cent polymorphonuclear cells, 33 per cent lymphocytes and 1 per cent eosinophils. The urine showed an alkaline reaction, a specific gravity of 1.014, a slight trace of albumin without casts and about 1 to 2 red blood cells per high power field.

Labor progressed normally and at about 4 p. m. on the day of admission the cervix was completely dilated. Two hours later the patient was delivered spontaneously of a normal female infant by left occipitoanterior presentation. The placenta was also expelled spontaneously, approximately fifteen minutes later. The general condition of the patient was good when she was returned to her room. The uterine fundus was firm and there was only a moderate amount of bleeding, which subsided completely by 9 p. m. About 6:30 a. m. the next day profuse vaginal bleeding was noted. It could not be definitely determined just when during the night bleeding had commenced. On examination at 7 a. m., the patient presented the usual clinical manifestation of severe loss of blood and the uterus was palpable at the umbilicus. Ergot by hypodermic was given at once, followed by a uterine stimulant by mouth, which was to be repeated three times during the day. She was also given an intravenous injection of 1,000 cc. of 10 per cent dextrose in saline solution while preparations were being made for a blood transfusion. Because a compatible blood donor was not immediately available, it was decided to give the patient 250 cc. of normal human plasma ("Lyovac" Rapidly Lyophilized Normal Human Plasma, Sharp and Dohme) which had been kept available for just such an emergency. In the meantime, the patient was reacting satisfactorily and, prior to the administration of the plasma, had improved considerably. The plasma was diluted and administered exactly as specified in the directions accompanying the outfit. No cross matching tests were performed, since the circularized instructions on the use of the plasma specifically state that such tests are entirely unnecessary. The injection of the plasma was slow, having lasted about an hour and fifteen minutes. About twenty minutes after the completion of the transfusion the patient suddenly experienced a chill, which was accompanied by nausea and vomiting. The pulse rate rose to 160 a minute and the patient repeatedly expressed fear of impending death. The poor condition and general appearance of the patient, as was later admitted by the attending physician, convinced him also that death was impending. The patient presented a typical picture of acute shock. Her face was ashen gray and her skin cold and clammy. Her voice was feeble and her pulse almost imperceptible. She

was given 1 cc. of epinephrine and caffeine with sodium benzoate by hypodermic as well as applications of external heat. The reaction lasted about thirty minutes, then began to subside. Her color gradually improved and the pulse rate dropped to 100 a minute. The weakness, however, persisted for a number of hours.

The following day a whole blood transfusion of 500 cc. was given to the patient without any untoward results. The donor was her brother, also of group A, and his blood was found to be compatible with her blood on cross matching prior to the transfusion. Following this, she made an uneventful recovery and was discharged cured on the tenth hospital day.

A catheterized specimen of urine, which was obtained immediately after the reaction, showed 1 to 2 red blood cells per high power microscopic field. Since similar conditions were noted on admission, they cannot be ascribed to the transfusion reaction. However, subsequent examination showed a persistence of the hematuria, which at times became exacerbated. Thus, on the fifth day after the reaction the urine continued to show albumin, a moderate number of hyaline and granular casts and many more red cells than had been noticed previously. The urinary conditions did not return to normal until just before her discharge from the hospital.

As soon as the reaction occurred, the laboratory was called on to determine, if possible, the cause of the accident. The usual routine "check-up" tests were then performed, consisting of the regrouping of the patient's blood, cross matching of the patient's cells and plasma solution, as well as various tests on the plasma for atypical agglutinins or hemolysins, and for formed elements including bacteria and the like. Fortunately we had in our possession a sample of the patient's blood which was obtained prior to the plasma transfusion. (This specimen of blood had been obtained with the intention of grouping and cross matching for a whole blood transfusion, which was the original intention of the attending physician. Since no compatible donor was available at the moment, however, it was decided to give the patient a plasma transfusion instead.) Examination of this specimen of blood showed it to be group A (MN) and on being mixed with a sample of the plasma solution which had been salvaged from the flask from which the patient received the plasma transfusion a most pronounced and immediate agglutination of the red blood cells occurred. Various dilutions of this plasma solution were then prepared, ranging from 1:2 to 1:8. These dilutions actually represented 1:4 to 1:16 dilutions of the original dry plasma, since the plasma solution that had been injected into the patient was prepared by dissolving the dry plasma in equal parts of distilled water. All dilutions up to and including 1:8 readily agglutinated the patient's cells in vitro. Similar results were obtained with fresh specimens of the patient's blood and the same dilutions of plasma. Apparently the transfusion reaction did not alter the patient's blood so as to mask the reactions in vitro. It is also noteworthy that dilutions of the plasma as high as 1:16 with water failed to hemolyze the patient's cells. These tests were performed with the direct coverslip preparation at room temperature as well as with the more sensitive centrifuge and incubation technic. The readings were all definite and recurred consistently with each repeated examination, leaving no doubt as to the validity of the observations.

The diluted plasma was also tested with the blood of 10 other persons, 6 of group A, 2 of group B and 2 of group O. It agglutinated the cells of all except those of group O, indicating that the responsible factor for the agglutination in vitro was not an individual one peculiar to the patient.

Studies made on the patient's blood and the plasma solution for the Rh factor, while disclosing that the patient was Rh positive, failed to show, however, any anti-Rh agglutinins in the plasma, or in the patient's serum. Furthermore, the plasma solution failed to agglutinate other known Rh positive bloods. The Rh factor, therefore, can be absolved from responsibility in the reaction that occurred in this case. The possibility of an isoimmunization by an antigen other than Rh during the course of her present pregnancy can also be excluded in this case, since the patient's serum failed to show any atypical agglutinins and also since the child is normal.

Dr. Philip Levine of the Beth Israel Hospital, Newark, N. J., cooperated by performing the Rh tests on the specimens of blood and plasma in this case.

From the Departments of Pathology and Obstetrics of Prospect Heights Hospital and the Department of Pathology of the Cumberland Hospital.

COMMENT AND CONCLUSION

Although the exact cause for the reaction in this case is not entirely clear, the evidence points strongly to an incompatibility between the patient's cells and the plasma solution injected. So pronounced an agglutination as occurred in vitro between the patient's blood and so highly a diluted plasma cannot be dismissed too lightly. While it is true that there was no decided hemolytic process observed after the reaction, the clinical picture was otherwise typical of a severe transfusion shock. Fortunately the reaction did not prove fatal. Certain it is, however, that if the agglutinative titer of the plasma (even though demonstrable in vitro only) had been known to the physician prior to the injection of the plasma, he would not have dared to proceed with the transfusion. With the knowledge of the results in this case as subsequently disclosed by the cross matching tests, even the most enthusiastic supporters of the theory that plasma may be safely given without cross matching would hesitate to inject this particular plasma solution. Obviously, unless pretransfusion cross matching tests are performed one cannot hope to be able to detect such potentially troublesome plasma solutions. Yet no one will deny that the patient is entitled to this added precaution whenever possible, despite the so-called factor of safety that has been built up about pooled plasma. Most of the plasma transfusions given today lend themselves to this precautionary measure, for in very few instances is the emergency so great that seconds count. Such dire emergencies are excluded from present consideration; all agree that such emergencies know no law.

In this case a cross matching test of the plasma with the patient's blood prior to the transfusion might have spared the patient a near-fatal reaction. It should serve as a warning against similar instances in the future.

DEATH FOLLOWING THE INTRAVENOUS ADMINISTRATION OF DIODRAST

HAROLD L. GOLDBURGH, M.D., and SAMUEL BAER, M.D.
PHILADELPHIA

In view of the extensive and widespread use of radiopaque solutions in excretory urography, it is not surprising that numerous toxic effects of the solutions used have been reported. Nausea, vomiting, shock, urticaria, edema of the glottis, rhinitis and various other manifestations of hypersensitivity have been known to occur.¹ Arterial and venous thromboses resulting from the use of diodrast or a preparation similar to it have been reported in the American and foreign literature.² Fatalities following the intravenous use of diodrast, however, have been exceedingly rare, when it is considered that millions of these injections have been given.³ The occurrence of such a fatality forms the basis for this presentation.

REPORT OF CASE

Mrs. M. G., aged 67, was admitted to the medical wards of the Jewish Hospital on Oct. 23, 1941 for treatment of diabetes mellitus. She was known to have had diabetes for about fifteen years and had been attending the cardiac, metabolic, medical, arthritic and allergic outpatient departments of the hospital off and on for twenty years. Since her diabetes was only moderately well controlled she was hospitalized for standardization.

On admission she presented the usual symptoms that one would expect to find in an elderly woman suffering from uncontrolled diabetes, hypertensive heart disease and degenerative arthritis. She also complained of dyspnea and a chronic non-productive cough. There was no demonstrable cardiac failure. The heart was enlarged to the left, and systolic murmurs were heard at the apex and over the aortic area. Generalized

arteriosclerosis and hypertension were present. Preliminary laboratory studies revealed hyperglycemia, glycosuria and a moderate hypochromic anemia.

During an attempt to regulate her diabetes the dyspnea became more severe and basal rales and mild bilateral pleural effusion developed. Serial electrocardiograms revealed the presence of progressive myocardial damage. The electrocardiographic changes, together with the slowly developing cardiac failure and a rapid sedimentation rate, made us suspect the presence of a silent subacute myocardial infarction. Under rest and digitalization her cardiac status rapidly improved.

November 11, eighteen days after admission, an intravenous urogram was done with diodrast, because of a palpable tender right kidney. The film revealed kidney shadows that were normal in size and position, but because of inadequate outlining of the urinary tract a repeat urography was advised. On November 18 at 3 a. m., the patient had an attack which seemed similar in every respect to the asthmatic attacks she had experienced fifteen years previously. She had had no asthmatic seizures for many years. Within forty-eight hours the respiratory difficulty disappeared and physical examination of the chest became negative.

On November 20 she was sent to the x-ray department for another intravenous urogram. A few drops of the diodrast were placed under the tongue, and when no reaction became manifest in from ten to fifteen minutes injection of the diodrast was begun. The injection consisted of 25 cc. of 35 per cent diodrast given in a period of seven minutes. Within five minutes the patient became deeply cyanotic and had a convulsive seizure. Unconsciousness developed and respirations gradually decreased, though the pulse was still perceptible. Despite all attempts at resuscitation, including the use of epinephrine and artificial respiration, the patient died within twenty minutes of the beginning of the injection. Two features particularly noted at death were the deep cyanosis and the well defined hepatomegaly. The liver, which had been barely palpable that morning, was at death enlarged about 6 inches (15 cm.) beneath the right costal cage. Permission for autopsy was denied.

COMMENT

We believe that this patient suffered a fatal anaphylactic reaction following the intravenous injection of diodrast. Whether the first injection of diodrast nine days previously acted as a sensitizing dose we cannot say.

Cumming and Chittenden² listed 5 deaths that were allegedly due to contrast mediums used in excretory urography. One or perhaps 2 of these deaths may not be attributed directly to the solution injected. Crane⁴ reported 2 deaths due to the intravenous administration of diodrast. The 1 case in which an autopsy was done presented at autopsy a typical picture of anaphylactic shock. Dolan⁵ also reported a fatal anaphylactic reaction following the intravenous administration of but 3 cc. of diodrast. The case he reported bears a striking similarity to ours, and we concur completely in his presentation of the death as one due to allergy. Certainly it is not the concentration of the iodine or the speed of injection that is responsible. Robb and Steinberg⁶ have reported almost 500 injections of from 30 to 75 cc. of 75 per cent diodrast, injected within two seconds, without a serious reaction. At the Mayo Clinic,⁷ 25,000 intravenous injections of diodrast have been given without a fatality.

In view of the clinical picture presented by our case and the strong similarity to the one reported by Dolan, we feel that we should reemphasize his recommendations. A detailed allergic

history should be taken of every patient prior to excretory urography, and the methods for testing the patient's sensitivity discussed by Dolan should be rigidly adhered to.

SUMMARY

A fatality due to allergy followed the intravenous administration of diodrast. This is the ninth death recorded in the American literature. There should be extreme caution exercised in the intravenous use of this preparation in patients with a history of asthma or sensitivity to iodine.

1932 Spruce Street—6300 Rising Sun Avenue.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Acting Secretary.

NIKETHAMIDE.—Diethylamide of pyridine-3(β)carboxylic acid.—Pyridine-3(β)carboxylic acid diethylamide.—The diethylamide of nicotinic acid—N,N-diethyl nicotinamide.— $C_8H_{11}N.CON(C_2H_5)_2$.

Actions and Uses.—Experiments involving several species of animals indicate that the action of nikethamide is mainly on the central nervous system. In animals the drug appears to stimulate medullary centers, giving rise to an increased rate and depth of respiration and to peripheral vasoconstriction. Possibly the vasoconstriction may be in part due to a peripheral action of the drug. In animals its administration usually results in some increase in blood pressure, but this may be preceded by a temporary and sudden lowering of the pressure. Claims have been made for the use of nikethamide as an agent to raise blood pressure in human beings, but the results are not consistent; it has been suggested that any rise in blood pressure may be secondary to improved respiration and to stimulation of the reflex centers. Small doses in experimental animals exert no action on the coronary vessels, but larger doses may increase the coronary flow. However, clinical evidence for the use of nikethamide to promote increased coronary blood flow is not conclusive.

Nikethamide has been used clinically as a cardiac stimulant, but the majority of published reports do not reveal it to be especially efficient and it is probable that the cardiac effect does not depend on a direct action on the myocardium. Most experiments with carefully adjusted doses show no consistent increase in the amplitude of the heart beat, and any beneficial effect in cases associated with imperfect filling of the right side of the heart may be due to a respiratory effect leading to an increased oxygen exchange in the lung. The relief of respiratory distress in cardiac disease, as in paroxysmal dyspnea, may result from the effect on the respiratory system. At the present time there is no justification for the use of nikethamide in association with chronic myocardial failure, myocarditis, coronary disease (coronary thrombosis or coronary sclerosis) and angina pectoris. The analeptic action of nikethamide suggests its usefulness in combating acute respiratory depression from anesthetics, alcoholic intoxication and hypnotics. However, it is not clear that nikethamide is superior in this respect to other available drugs, especially in cases of barbiturate poisoning. Because of its additional action on peripheral vascular tone it appears to be of benefit in cases of acute circulatory failure occurring during the course of surgical procedures or pneumonia. However, nikethamide is contraindicated in pneumonia unless circulatory collapse supervenes.

Dosage.—Nikethamide is available as an aqueous solution, 25 per cent W/V, for oral and for subcutaneous, intramuscular or intravenous administration, but in emergencies no benefit can be expected from oral administration. The latter is usually true also for subcutaneous administration. The drug should preferably be given intravenously. Because nikethamide, after intravenous administration, is rapidly inactivated, the dose depends on the rate of injection. When doses larger than 3 cc. are given, the administration should be slow and the general reaction of the patient should be watched. It should be remembered that large or toxic doses produce convulsions and may cause death from respiratory failure. The dose may be repeated at intervals according to the needs of the patient.

Tests and Standards.—

Nikethamide occurs as a clear, colorless to very pale yellowish, somewhat viscous liquid, possessing a slight characteristic aromatic odor and a peculiar bitter taste. Nikethamide is miscible in all proportions with water, alcohol and ether. The refractive index of nikethamide is 1.522 to 1.524 at 25°C.; the specific gravity is not less than 1.058 nor more than 1.066 at 25°C. The p_H of a 25 per cent aqueous solution (W/V) of nikethamide made with freshly boiled and cooled distilled water is not below 6.0 or above 6.5, as determined by means of a glass electrode. Nikethamide freezes on standing in the cold and melts at from 20 to 26°C.; it resolidifies easily when cooled, provided some fragmentary crystals are present. Nikethamide boils at 128 to 129°C. under a pressure equivalent to 3 mm. of mercury, at 158 to 159°C. under a pressure equivalent to 10 mm. of mercury and at about 296 to 300°C. with some decomposition, under a pressure of one atmosphere.

Dissolve about 3.0 Gm. of nikethamide in 10 cc. of 10 per cent sodium hydroxide solution and warm on a water bath for thirty minutes; the solution yields the odor of diethylamine. Allow the solution to cool, acidify with dilute hydrochloric acid to a p_H of 3.6 (slightly acid to congo red); collect the fine, white precipitate on a filter, wash with water and recrystallize from 5 cc. of water; collect on a filter and dry at 100°C.; the nicotinic acid obtained melts at 235 to 238°C.

Heat a few drops of nikethamide with 1 Gm. of sodium carbonate a strong odor of pyridine results.

Dissolve 10 Gm. of nikethamide in 90 cc. of water; the solution is clear, nearly colorless and free from the odor of pyridine; it yields only a faint odor of diethylamine. The solution will respond to the following tests: Add to 5 cc. of solution 5 cc. of normal hydrochloric acid and 5 cc. of a solution made by dissolving 12 Gm. of potassium iodide, 3 Gm. of bismuth subnitrate and 3 cc. of concentrated nitric acid in sufficient water to make a volume of 50 cc.; a heavy reddish orange precipitate forms immediately. Add to 5 cc. of the solution 5 cc. of copper sulfate solution and 5 cc. of potassium thiocyanate solution; shake the mixture a flocculent light green precipitate forms. A 10 cc. portion of the solution is yellow on the addition of 5 drops of methyl red indicator (free acid) but turns red on the addition of 0.1 cc. of tenth normal hydrochloric acid (limit of free diethylamine). A 5 cc. portion of the solution becomes only faintly opalescent on the addition of 0.5 cc. of nitric acid and 0.5 cc. of silver nitrate solution (chloride).

Mix 5 cc. of the solution with 5 cc. of sulfuric acid, cool and cautiously overlay 5 cc. of ferrous ammonium sulfate solution; no brown color appears at the interface (nitrate). Add 5 drops of dilute sulfuric acid to 5 cc. of the solution; extract twice in a separatory funnel with 20 cc. portions of a mixture of 3 parts of chloroform and 1 part of isopropyl alcohol; combine the extracts, filter, evaporate to dryness on a steam bath and dissolve the dry residue in 10 cc. of boiling water. When the solution is cool, add 0.1 cc. of tenth normal sodium hydroxide and 1 drop of phenolphthalein indicator, the solution turns red (methic acid).

Warm 10 Gm. of nikethamide for one hour with 3 cc. of dilute hydrochloric acid and 6 cc. of water, cool and add 5 cc. of sodium hydroxide solution; the solution yields no distinct yellow color (foreign organic impurities).

A solution made by dissolving 1 Gm. of nikethamide in 5 cc. of carbon disulfide is clear (water).

Ash 1 Gm. of nikethamide; the residue is negligible. Transfer 25 mg. to 50 mg. of nikethamide, accurately weighed, to a 50 cc. Kjeldahl digestion flask and add 1 cc. of water and 1 cc. of concentrated sulfuric acid. Heat the mixture gently until most of the water has been removed and continue heating vigorously for fifteen minutes, cool, add 3 cc. of water, transfer to a micro Kjeldahl distilling apparatus, add 5 cc. of sodium hydroxide solution (1:1) and distill into a flask containing 10 cc. of 2 per cent boric acid solution colored with methyl red solution (1 drop in each 20 cc.). Titrate the solution with fiftieth normal sulfuric acid to a pink color, matched against a prepared blank. Each cubic centimeter of fiftieth normal sulfuric acid is equivalent to 3.565 mg. of nikethamide. The amount of nikethamide found should be not less than 99 per cent nor more than 100.5 per cent.

The following dosage forms have been accepted:
GEORGE A. BREON & CO., INC., KANSAS CITY, MO.

Solution Nikethamide 25% W/V: 2 cc. and 5 cc. ampuls

THE LAKESIDE LABORATORIES, INC., MILWAUKEE.

Solution of Nikethamide, 25% W/V: 2 cc. and 5 cc. ampuls and 15 cc. vials with dropper for oral use.

Solution of Nikethamide, 25% W/V: 15 cc. vial for injection with 0.5% chlorobutanol.

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Nikethamide: bulk.

Solution Nikethamide 25% W/V: 1½ and 5 cc. ampuls; 15 cc. vials for oral administration

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Solution Nikethamide 25% W/V: 1.5 and 10 cc. ampuls; 3 ounce bottle.

MENADIONE (See THE JOURNAL, Jan. 17, 1942, p. 226)

The following dosage form has been accepted:

MCNEIL LABORATORIES, PHILADELPHIA.

Capsules Menadione: Each soft elastic black capsule contains 2 mg. of menadione dissolved in corn oil.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1941, p. 519).

The following dosage forms have been accepted:

GEORGE A. BREON & CO., INC., KANSAS CITY, MO.

Sulfathiazole-Breon (powder): bulk.

Tablets Sulfathiazole-Breon: 0.5 Gm. (7½ grains).

HOSPITAL SERVICE IN THE UNITED STATES

TWENTY-FIRST ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

TABLE OF CONTENTS

HOSPITAL DATA, STATISTICAL TABLES, MAPS AND TEXT.....	PAGES 1053-1066
INTERNSHIPS, RESIDENCIES AND FELLOWSHIPS.....	PAGES 1067-1070
LIST OF REGISTERED HOSPITALS.....	PAGES 1071-1134
APPROVED SCHOOLS FOR OCCUPATIONAL THERAPISTS, PHYSICAL THERAPY TECHNICIANS AND CLINICAL LABORATORY TECHNICIANS.....	PAGES 1135-1142

The twenty-first annual census of hospitals by the Council on Medical Education and Hospitals of the American Medical Association for the year 1941 discloses a total of 6,358 registered hospitals. This is an increase of 67 hospitals over the number on the Register one year ago.

The growth of hospital facilities for the past year was the equivalent of one 269 bed hospital for every day, Sundays and holidays included.

The capacity of registered hospitals amounts to 1,324,381 beds and 66,163 bassinets. There are 98,136 more beds and 4,224 more bassinets than one year ago.

These figures refer only to inpatients, or bed patients, and do not include outpatients or ambulatory patients, a similar number of whom visit hospital outpatient departments.

The total patient days of hospital service for 1941 was 396,769,235, an increase over 1940 of 21,190,649. The number of patient days was obtained by multiplying the average daily census of all registered hospitals by 365.

The average occupancy rate in general hospitals was 68.2 per cent compared with 70.3 per cent for the preceding year.

c. Planned. Construction pending.....				108

* As of Dec. 31, 1941.

For thirty-one years the average net increase in hospital facilities was around 25,000 to 30,000 beds each year, as contrasted with 98,136 beds increase between the census of 1940 and the census of 1941.

The present report covers approximately the calendar year 1941. Because of differences in fiscal years, not all hospitals supplied data for the calendar year 1941. The minority, including mainly the smaller hospitals, reported for the twelve month period ended Sept. 30, 1941.

Reports were received from 6,318 hospitals out of the total of 6,358 registered hospitals, or a record of 99.4 per cent.

The total number of patients that entered registered hospitals during the year was 11,596,188 as compared with 10,087,548 for the previous year, an increase of 14.95 per cent. Patients entered hospitals, therefore, at the rate of one for each 2.7 seconds day and night throughout the year, including Sundays and holidays.

The average census of patients in hospitals was 1,087,039, an increase of 60,868 over the previous year.

Special acknowledgment and appreciation are extended to the many hospital superintendents and assistants, chiefs and members of staffs, and other officials who have cooperated by supplying details that made possible the elaborate and complete statistics and lists published in this issue. Much credit is due to county and state medical organizations and health commissioners for their prompt and efficient help.

The average number of idle beds in general hospitals for 1941, as indicated in the reports, was 169,884. In 1940 it was 137,200.

This drop in occupancy rate is readily explained by the unusually rapid increase in hospital facilities, which temporarily got ahead of the occupancy rate. There has been a rise in occupancy rate in general hospitals since 1933, for example, when it was only 59.9 per cent. In the same time there has been a considerable increase in general beds.

The average stay per patient in general hospitals has been reduced from fourteen days in 1935 to twelve days

in 1941, an average saving of two days per patient. For all the 10,646,947 patients in general hospitals in 1941 the aggregate saving was 58,339 years. Figuring this saving at \$4 a day, the cost of hospitalization for each patient admitted was \$8 less than it would have been in 1935, the equivalent of a saving of \$85,175,576 in hospitalization costs.

One person for each 11 in the United States entered a hospital as a patient in the year 1941, using the 1940 census and counting only bed patients.

ANNUAL CENSUS OF HOSPITALS

In each annual census blank are certain standard questions such as number of beds, bassinets, births, patients admitted, average census of patients, also lists of staff doctors and interns. In addition to these perennial data, each questionnaire includes certain questions that are of importance at the particular time. Each succeeding questionnaire, therefore, is different from the preceding, and the tendency is for them to expand somewhat in length and complexity. The policy of the Council always has been to ask only for data that are important and to make use of all the information that is obtained.

The list of registered hospitals beginning on page 1071 omits additions to hospital facilities that may have been made by certain departments of the federal government since the publication of the last previous issue of the Hospital Number, March 15, 1941. The statistical tables, however, include data on all registered hospital facilities.

The hospitals that are approved by the Council for internships and for residencies in specialties received a questionnaire that is more comprehensive than the one used for all the other registered hospitals.

In the list of registered hospitals following this article the hospitals that the Council approves for intern training are marked with a five point star (*) and those approved for residencies with a plus sign (+). Some detailed information regarding the hospitals approved by the Council are given on a later page under the heading of Internships, Residencies and Fellowships.

It is not necessarily true in all cases that the approved hospitals have essentially better equipment or give better care to patients, but because a hospital assumes the function of training interns and residents and is approved for that purpose it becomes necessary for the Council to check on the teaching facilities and functions in those hospitals in addition to the general information solicited from all other registered hospitals.

COOPERATION BY AMERICAN COLLEGE OF SURGEONS AND A. M. A. ON CENSUS BLANK

This year, for the second time, the questionnaires used by the Council represent a combination of the annual census blank of the American Medical Association and the annual questionnaire of the American College of Surgeons. Cooperation of the College and the Council reduces the work of filling out questionnaires by hospitals. It also facilitates the gathering of essential data required by the two cooperating organizations for their use and for the public. The officials of the A. M. A. and the College, and their office staffs, worked together to design a questionnaire that would elicit more information with fewer questions and achieve greater uniformity and simplification in the use of terms. All the hospitals that are fully approved as meeting the minimum standards of the American College of Surgeons are designated with a delta (Δ) in the list of registered hospitals, page 1071.

The accompanying tabulation shows the increase in hospital facilities bearing the approval of the American College of Surgeons.

Each organization has its own distinctive standards, administration, inspections and approved lists. Approval of a given institution by one organization does not in any way affect the initiative and the responsibility of

the other organization with regard to the approval of that institution. There is cooperation as to the joint questionnaire, correlation of inspection itineraries and mutual courtesy in the use of symbols to designate each other's approvals.

REGISTRATION AND APPROVAL

Registration means the inclusion of the hospital in the list published in the Hospital Number of THE JOURNAL and in the American Medical Directory. The Essentials of a Registered Hospital are employed in such a way as to raise the standards of hospitals and to point the way to better service.

Approval, on the other hand, means specific endorsement of hospitals for educational purposes, the fitness for which is determined by observation, inspection and

Hospitals Fully Approved by the American College of Surgeons in the United States

	Hospitals	Beds	Bassinets	Patients Admitted
1941.....	2,307	726,531	44,330	8,334,546
1940.....	2,261	652,634	41,697	7,495,253

comparison with definite requirements for the intern training and residencies.

Registration is a basic recognition, extended to all the hospitals and related institutions concerning which the Council has no evidence of irregular or unsafe practices. Approval is designation of certain registered institutions by the Council for internships, residencies and fellowships; or by the American College of Surgeons as unconditionally meeting its minimum standards. Registration of hospitals is governed by the

Essentials of a Registered Hospital, adopted by the House of Delegates in 1928 and revised in 1939.

The term approved, as used by the College of Surgeons, may be applied to those registered hospitals that meet the minimum standards of the College.

GOVERNMENT HOSPITALIZATION

Federal hospitals admitted 1,268,112 patients, including those of the Veterans Administration, Army, Navy, Public Health Service, the Departments of Justice and of Indian Affairs, the Tennessee Valley Authority and the National Youth Administration. The average census of patients in federal hospitals was 118,890.

FACILITIES UNDER STATE AND LOCAL GOVERNMENT

State hospitals number 530 and show an increase of 9 during the year. The capacity is 600,320 beds as compared with 572,079 beds a year ago. Bassinets now number 1,572. State hospitals admitted 620,231 patients and the average daily census was 561,620, an increase of 36,957 admissions and of 21,626 in the average daily census over the previous year.

There are now 512 county hospitals where there were 514 a year ago. The capacity of county hospitals decreased to 98,227 beds. Bassinets have slightly increased to 3,288. Patients admitted to county hospitals were 643,740 as compared with 615,247 for the preceding year. The average census of patients was 83,214, reduced from 87,029.

City hospitals, numbering 337, reached an increase of 5 over the previous year, and the bed capacity increased to 78,060 and bassinets to 5,045. The number of patients admitted was slightly increased to 999,559, and the average census reduced from 63,644 to 61,019.

City-county hospitals are fewer in number, capacity and average census but increased during the year in number of patients admitted from 126,487 to 130,960.

HOSPITAL FACILITIES UNDER NONPROFIT ORGANIZATIONS

For convenience, the hospital work of nonprofit organizations is shown under "Church Related Institutions" and "Other Nonprofit Associations."

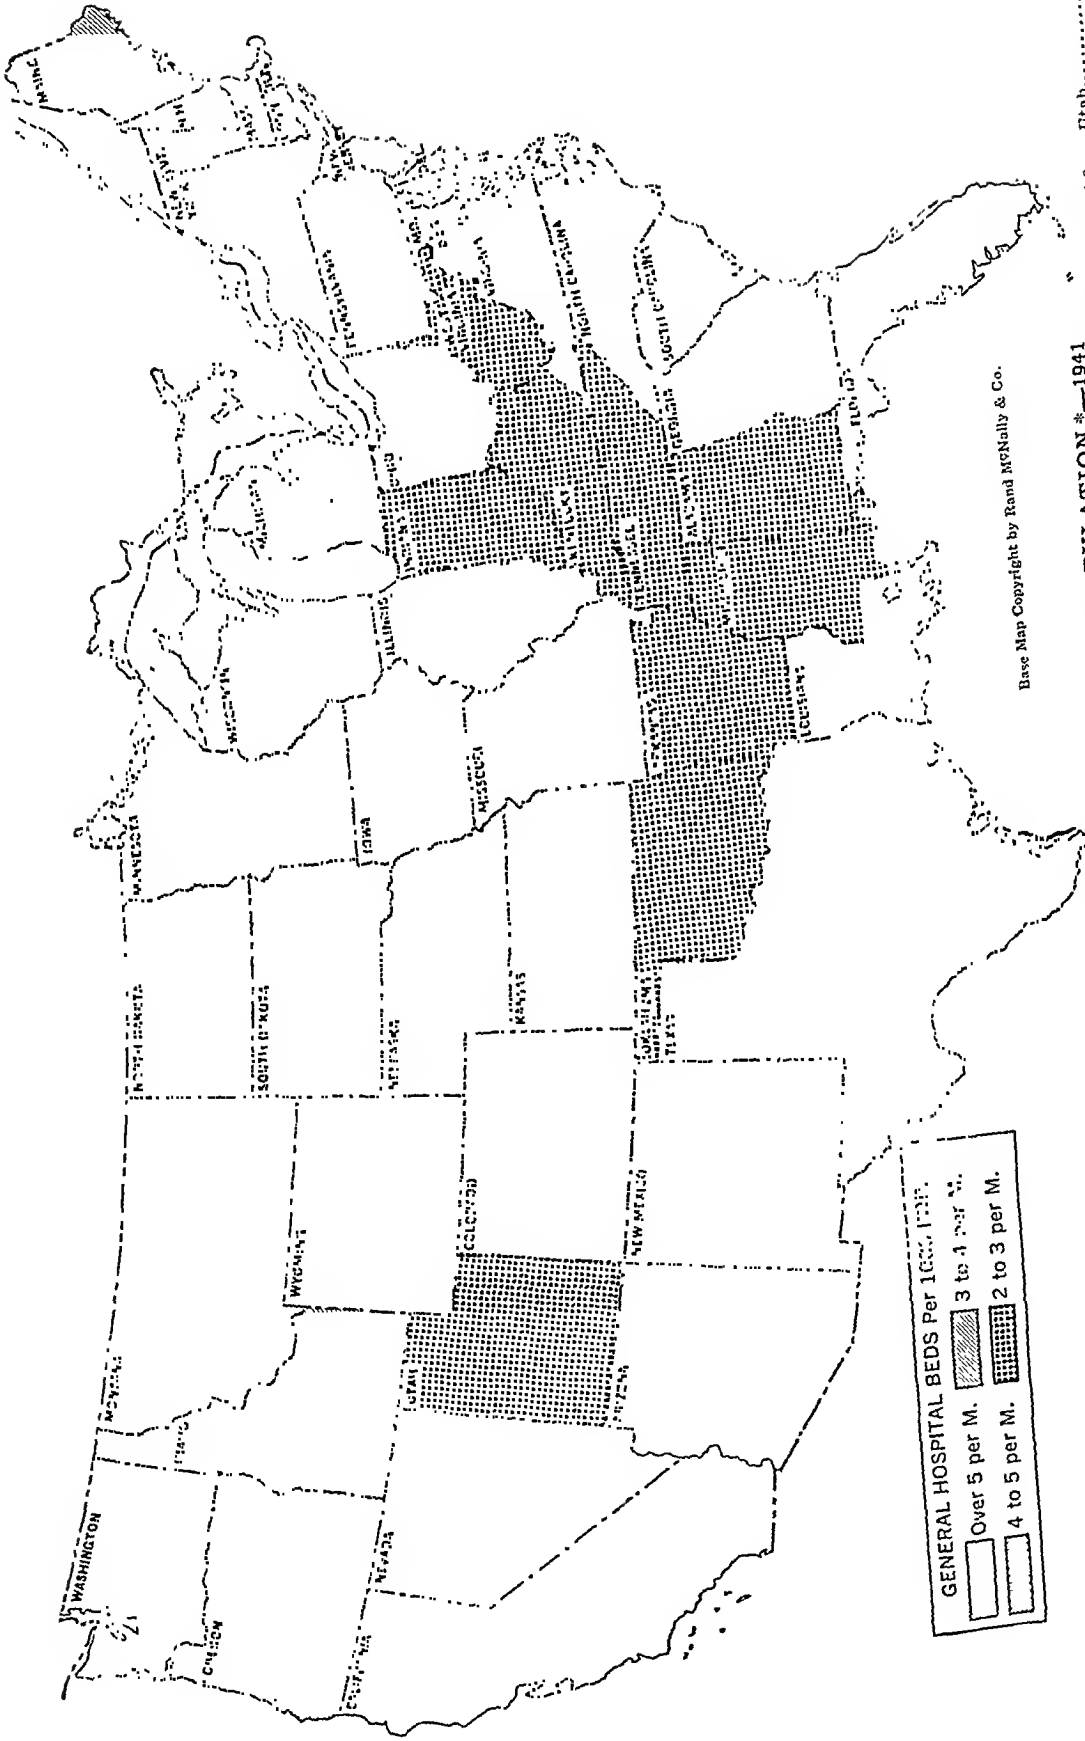

Church related hospitals number 993, which is 5 fewer than a year ago, but the group shows very substantial

increases in its facilities, which now number 123,331 beds and 20,145 bassinets. There were 2,961,594 patients admitted, and the average census was 90,195.

The other nonprofit organizations have increased in number from 1,903 to 1,917. They have 182,140 beds

1939	329	96,338	523	560,575	5,374	538,113	6,226	1,195,026
1940	336	103,828	521	572,079	5,434	545,238	6,291	1,226,245
1941	428	179,202	530	600,320	5,400	544,859	6,353	1,324,381

the total number of nonprofit institutions now is 2,910 with a capacity of 305,471 beds and 46,567 bassinets. Admissions to nonprofit institutions amounted to 6,892,735, the admissions for the previous year being 6,254,850. The average census was 222,667 as compared with the previous year, when it was 210,764.

FACILITIES UNDER PROPRIETARY CONTROL

The total of facilities now under proprietary control is 1,584 hospitals having a capacity of 53,399 beds and 8,102 bassinets. Patients admitted numbered 1,040,851 with an average census of 32,480.

Proprietary hospitals fall into two groups, those maintained by individuals and partnerships and those that are owned by corporations which have the privilege of making a profit or which, in other words, are unrestricted as to profit.

Individual and partnership hospitals, it will be noticed, have declined in number since the year 1927. They now number 1,149 with a capacity of 28,760 beds and 5,054 bassinets. Admissions increased last year to 545,884 and average census to 16,582.

The corporations unrestricted as to profit have 435 hospitals as compared with 449 a year ago. The number of beds has decreased in the past year to 24,639. There are 3,048 bassinets. The patients admitted increased to 494,967 and the average census rose to 15,898.

FIGURES ON ALL NONGOVERNMENTAL FACILITIES

The final, or total, column of table 1, headed "Total Nongovernmental," shows a tendency toward increase in the average size of those hospitals rather than in number. Total nongovernmental hospitals is now 4,494 as compared with 4,524 one year ago. Present capacity is at a peak of 358,870 beds and 54,669 bassinets. Patients admitted in all nongovernmental hospitals numbered 7,933,586 as compared with 7,218,544 in 1940. The average census was 255,147 as compared with 241,499 a year ago.

WHERE CHANGES IN CAPACITY OCCURRED DURING 1941

For thirty-one years the average annual increase in the capacity of hospitals had been in the neighborhood of 25,000 to 30,000 beds. The census for 1941, how-

ever, showed a remarkable increase, which is astonishing even for this unusual period.

During 1941 there was a net increase of 98,136 beds in all hospitals. State hospitals gained 28,241 beds, church related institutions 2,522 beds and other nonprofit hospitals 4,459 beds. There were losses in bed capacity in county hospitals of 4,113 beds, city hospitals 985, city-county hospitals 1,595 beds, individual and partnership hospitals 198, corporation hospitals (unrestricted as to profit) 469. This makes a net increase of 98,136 for the year, or the equivalent of one 269 bed hospital for each day of the year, Sundays and holidays included.

REDUCED AVERAGE STAY PER PATIENT IN GENERAL HOSPITALS, COMPARING 1935 AND 1941

The average length of time spent in general hospitals per patient in 1941 was twelve days. In 1935 it was fourteen days. The very important thing is that there has been a saving of two days, and this saving when applied to all of the 10,646,947 patients who used general hospitals in 1941 means an aggregate saving of 58,339 years. The record achieved by each type or group of hospitals, according to ownership or control, is shown in the table entitled "Average Length of Stay per Patient in General Hospitals, 1935 and 1941." In that period the length of stay in governmental general hospitals dropped from twenty-two to eighteen and in non-governmental general hospitals from eleven to ten days.

Further analysis shows that the general hospitals operated under federal auspices accomplished a reduction from thirty-six days to twenty-one days, state from twenty-one to eighteen days, county from twenty to eighteen days, city from sixteen to fifteen and city-county from seventeen to twelve days.

Continuing the comparison of 1935 and 1941, in church related hospitals the average stay dropped from twelve days to ten days and in all nonprofit associations from eleven days to ten days. Only the hospitals operated and owned by individuals and partnerships remained stationary at eight days; corporations for profit dropped from nine to eight days.

Average Length of Stay per Patient in General Hospitals, 1935 and 1941

	1935	1941

All general hospitals...	14 days	12 days

PERCENTAGE OF BEDS OCCUPIED

The occupancy rate of all registered hospitals was 82.1 per cent for the year 1941 as compared with 83.7 for 1940 and 80.1 for 1929.

Although there was a large increase in number of patients admitted to hospitals during the year, it does not necessarily follow that the rate of occupancy would be higher. Indeed, it appears that because of the rapid

turnover of patients—that is, the shorter stay per patient—the rate of occupancy is not much greater than in previous years. In general hospitals, for example, the rate of occupancy was 68.2 per cent as compared with 70.3 one year ago and 65.5 in 1929.

The fact of a reduced rate of occupancy in general hospitals during the past year must be taken in connection with the large addition of new general hospital

patients to the minute throughout the year night and day, Sundays and holidays included.

OCCUPANCY IN GENERAL HOSPITALS

The map entitled "Occupancy in General Hospitals" shows graphically the prevailing rate of occupancy by states. Underneath the map is given each state's occupancy rate. The map is of value to those who wish

facilities during the year. The church related hospitals were operated at an average occupancy of 73.1 per cent, as compared with 70.4 one year ago and 66.7 per cent in 1929. Corporations unrestricted as to profit were 64.5 per cent occupied as compared with 62.5 a year ago. Hospital administrators in general agree that the maximum optional percentage occupancy consistent with efficient service is not much in excess of 75.

The admission of patients to all hospitals is shown by the census of 1941 to have been at the average of 22

to compare with similar maps published in the Hospital numbers for preceding years. Of course no state has an even rate of occupancy of hospitals all over the state—in fact, the hospitals of a state may vary from the lowest to the highest rates. The states having an average occupancy of 50 to 60 per cent increased in number from 4 to 10 during the past year. There is still, as last year, one state whose general hospitals averaged less than 50 per cent occupied. Those having a rate of 60 to 70 reduced in number from 28 to 26,

in Nevada. Other states ranking high in the number of general hospital beds per thousand are: Arizona, 7.4; Wyoming, 6.0; California, 5.9; Massachusetts, 5.9; Washington, 5.8; Colorado, 5.7; Louisiana, 5.7; Florida, 5.1.

The outstanding fact to be observed is that those states which provide few beds are found to have a low

**TOTAL
NONGOVERNMENTAL**

the number of general hospital beds per thousand of population. The table also gives for each state the percentage of occupancy in general hospitals and the percentage of population that entered general hospitals during the year, as well as the 1940 population census of the states.

rate of occupancy and, of course, a small proportion of the population making use of hospitals. For example, Utah, with 2.1 general hospital beds per thousand, shows an occupancy rate of 55.3 per cent, and its general hospitals were used by 3.5 per cent of the state's population. Nevada, with 8 beds per thousand, had an occupancy rate of 63.4 per cent; 12.3 per cent of the population of the state made use of its general hospitals during the

65	Maine																									

year. Oregon, the twenty-fourth state, or midway point, in number of general hospital beds per thousand, shows an occupancy rate of 73.0 per cent, and 9.9 per cent of its population entered a general hospital. The District of Columbia is not comparable, evidently because of the use of its hospital facilities by a considerable number of persons not enumerated in its census of population.

Average figures for the entire country show 4.1 general beds per thousand of population, an average occupancy of 68.2 per cent and 8.1 per cent of the entire population entering general hospitals as patients.

The table serves to emphasize the fact that hospital facilities must be provided not according to any abstract formula but in accordance with the requirements of the people in the community under consideration.

The map entitled "General Hospital Beds per Thousand of Population" tells the story of general hospital facilities in graphic form.

BIRTHS IN HOSPITALS

Response to the question "How many live births in the hospital during the year?" brought a total of 1,404,940. The total number of births reported in the United States both in and out of hospitals is not obtainable for the year 1941. In 1940 it was 2,360,399. Increase in births in hospitals in 1941 over those in 1940 was 190,448, which is by far the greatest increase recorded for this item between any two consecutive years. The gain of 1940 over 1939 was 114,779. In 1929, the first year in which the annual census of hospitals recorded the hospital births, there were 621,896. The table on births in hospitals gives some indication as to just what groups of hospitals are furnishing the maternity services and also shows interesting trends. As to type of service general hospitals report 1,342,195 births, and maternity hospitals 51,484. There is considerable increase from year to year in the number of

births in the hospitals operated by federal and state governments as well as in the county and city hospitals. Church related hospitals reported the births of 463,111 infants as compared with 394,765 last year. Other non-profit associations reported 561,844 as against 485,236 last year.

The hospital births by states are given in the column headed "Births" in one of the accompanying tables.

There are nine states in which the number of births in hospitals exceeded 50,000, headed naturally by New York, which reported 180,037 births, followed by Pennsylvania 112,392, Illinois 99,997, California 85,763, Ohio 82,677, Michigan 69,670, New Jersey 60,761, Texas 59,564 and Massachusetts 57,642.

NUMBER OF PATIENTS OPERATED ON
IN ALL HOSPITALS

In this, the twenty-first, annual census all registered hospitals, including those approved and those not approved for intern or residency training, were asked for the first time to "indicate number of patients oper-

ated on." The numbers reported in answer to this question are published by states, alongside the number of patients admitted, in an adjoining table. The total number of patients operated on is 5,201,650, or 44.86 per cent of the patients admitted.

In making up the questionnaire for the census, much consideration was given to the wording of this and similar questions. The form of question just quoted was finally determined on as being the most appropriate for this time, since confusion sometimes results when attempts are made to define the various types of operative procedures.

The response to this question has been, in the main, quite satisfactory and the question was followed up whenever necessary. As would be expected, the states that reported the highest number of patients operated

on are New York 643,773, Pennsylvania 423,734, Illinois 374,171, California 314,995, Ohio 267,311 and Michigan 233,746.

Those states in which the number of patients operated on exceeded 50 per cent or more of all patients admitted were Rhode Island 55.22 per cent, Pennsylvania 54.71 per cent, West Virginia 52.55 per cent, Connecticut 51.92 per cent, New Hampshire 51.19 per cent, Indiana 51.13 per cent, Nebraska 50.68 per cent and Wisconsin 50.34 per cent.

The states in which the number of patients operated on were less than 35 per cent of all patients admitted

In response to the question as to the number of necropsies, there is reported a total of 125,640 necropsies, or 24.63 per cent of the number of deaths reported. Owing to the Council requirement of a minimum percentage of necropsies in the approved internship and residency hospitals and the fact that hospitals so approved had a majority of admissions, it is not surprising that the greater number of necropsies would be performed in the approved hospitals, which reported a total of 96,151. These hospitals, totaling 1,070, had an average necropsy rate of 38.4 per cent, whereas all other registered hospitals had a necropsy incidence of 11.3

DEATHS AND NECROPSIES IN ALL HOSPITALS

The census questionnaire included the question "Number of deaths." The same question had been included in the annual census for at least two previous years. The total number of deaths reported from all the hospitals was 510,158, or 4.4 per cent of the patients admitted. Considering that all hospitals are accustomed to furnishing this information, it is believed that the figures presented in the column headed "Deaths" are fairly accurate.

per cent on the basis of 260,068 deaths and 29,489 post-mortem examinations last year.

In view of the educational importance of necropsies, this subject is discussed at greater length in that part of the article relating to internships, residencies and fellowships.

TECHNICAL PERSONNEL IN HOSPITALS, 1941

The census of technical personnel in hospitals reported in THE JOURNAL of March 27, 1937 was the first that rendered information complete enough for practical use. At that time the data received were tabulated to present by states the number of hospitals employing technical assistants and the number employed. The current census includes four groups not

previously reported, i e medical record librarians, other librarians, medical stenographers and social service workers, thus enabling the Council to present a more complete picture of the services rendered in hospitals by trained personnel other than physicians.

In the present census the full time and part time workers are enumerated separately, which reveals that only 18 per cent of the 50,326 individuals enumerated are serving on a part time basis. The part time group not only includes persons who are employed part time because of economic reasons but also in some instances persons who are offering their services to institutions on a voluntary basis.

Comparison of data received from all hospitals with those from general hospitals indicates that general hospitals employ nearly 75 per cent of all technical personnel engaged in hospital work and 75 per cent of all the full time employees.

PHYSICIAN SUPERINTENDENTS, NURSING PERSONNEL,
PRACTICAL NURSES, ATTENDANTS AND ORDERLIES

It is found that 2,133 physicians are serving as superintendents or administrators of hospitals. The proportion of superintendents thus qualified is 33.54

Schools of nursing number 1,448 with 93,977 students. In 1926 there were 2,155 schools with 76,527 students, and in 1936, 1,478 with 72,174 students.

In response to the question as to how many graduate nurses, and also how many practical nurses, attendants and orderlies are employed at nursing by hospitals, we have the total of 112,842 graduate nurses, 17,332 practical nurses, 95,002 attendants and 24,837 orderlies.

HOSPITAL FACILITIES NOT IN THE REGISTER

The facilities that are omitted from the list of registered hospitals are of two types: first, those that follow methods and practices such as are generally recognized as unethical or dangerous and that therefore need complete change of policy before being recommended to the public. Their number at the present time is 542. Their capacity, according to the latest available information is 16,267, or less than two thirds of 1 per cent of the facilities furnished by the hospitals recognized in the Register.

A second class of facilities not appearing in the Register includes emergency stations, clinics, offices and so on, with some facilities for bed care attached or available. They are recognized as ethical and valuable auxiliary facilities to the hospital system. Most of these unclassified facilities have three to ten beds each, which are used as occasion demands. Some of them are sick-rooms attached to small custodial institutions. The bed capacity of these institutions, usually spoken of as unclassified, is too variable to be positively enumerated.

per cent. This proportion has not varied more than 1 or 2 per cent for over a period of ten years. A further analysis of the types of hospitals that are thus served by physicians will be made.

INTERNSHIPS, RESIDENCIES AND FELLOWSHIPS

(As of March 1, 1942)

NUMBER OF INTERNSHIPS

The increase of internships from 1914 to 1942 is illustrated in table A, showing the number of hospitals and available internships in relation to the annual output of American medical colleges. When the first list was published by the American Medical Association in 1914 there were 508 general hospitals approved by the Council, 2,667 internships available and 3,594 medical graduates. In addition there were 60 special hospitals and 35 state institutions and hospitals for the insane that offered a total of 428 internships later classified as residencies in specialties. Thus 603 general and special hospitals supplied 3,095 internships, but only 2,527 appointments were made, indicating that 1,067, or approximately 30 per cent of the medical graduates, did not seek additional hospital training.

Internships continued to increase as hospitals found a growing need for the services of interns not only to fulfil the educational requirements of the Council and the standardization program of the American College of Surgeons but to keep pace with the rapid progress of medical practice and the introduction of new methods of diagnosis and therapy. It was not until 1926, however, that available internships began to exceed the number of students graduating each year, although an exception occurred in 1922, when the senior class was considerably reduced on account of the earlier influence of the war. From then on there has been a steady increase in educational facilities for interns even beyond the annual needs of the graduating classes, which have remained fairly constant in size since 1934. Some of the increase has been produced by the qualification of additional hospitals, yet the enlargement of intern staffs resulting in many instances from an expansion of bed capacity or rising admission rate and average daily census has also been a significant factor. It should be noted that the proportion of medical graduates seeking hospital appointment has increased from approximately 70 per cent in 1914 to 99 per cent in recent years. This expansion of internships has been made possible by the whole hearted cooperation of a large number of hospitals throughout the country, which have not only supplied current needs but have created a sufficient reserve to meet any new demands that may be placed on them from time to time. According to reports received in January 1942, 7,228 internships are now available annually in the 732 hospitals approved for intern training by the American Medical Association.

NUMBER OF VACANCIES

While it would seem that the number of available internships has been excessive in recent years, it must be taken into consideration that many of the surplus appointments are filled by second year interns, foreign graduates and applicants from the medical schools of Canada and several of the Central and South American countries. In 1939, when there were 5,089 medical graduates in the United States, the approved intern hospitals reported a total of 7,448 interns actually on duty. According to information received at that time, the number of vacancies was only 317. Further reports also seem to indicate that the demand for interns has not greatly exceeded the supply of available candidates except perhaps in the last two years. In January 1940,

for example, after the annual reports on internships had been received, it was found that 176 hospitals had 344 vacancies: 60 in public hospitals and 284 in institutions under private control. By January 1941, however, the number of vacancies had increased to 615 in 270 hospitals, and reports received in January 1942 show a total of 1,128 unfilled positions in 437 of the hospitals approved for intern training (see table B). These institutions, however, employ 201 second year interns under the classification of mixed residencies, so that the present shortage might be considered as only 927. This coincides with the reports from the approved hospitals showing that 7,219 interns are currently employed whereas 8,181 positions are actually available.

FUTURE NEEDS

It is obvious that an exact balance cannot always be maintained between the number of available internships and the annual supply of medical graduates, since variations may frequently occur not only in the enrolment of medical students but also in the number of hospitals that wish to participate in the training of interns. In order that all students may obtain acceptable training during their fifth year of medicine, it is usually necessary that a surplus of qualified internships be available, as eligibility requirements and individual preferences may limit the assignment of interns in certain hospitals. When any considerable excess develops, however, it becomes increasingly difficult for many hospitals to secure sufficient interns to maintain a satisfactory educational program unless the training schedule can be bolstered by the addition of second year men. If this is not possible, a solution may perhaps be found in the establishment of mixed residencies or in the employment of salaried house officers outside the scope of an educational service. In many instances it will no doubt become necessary for the attending physicians and their assistants to take over some of the functions ordinarily assigned to interns and residents, although certain routine procedures might well be allocated to qualified nursing and technical personnel.

As regards future needs, it is encouraging to note that if medical students and interns avail themselves of the War Department plan described in *THE JOURNAL*, Feb. 21, 1942, pages 633-634 and secure deferment during their period of undergraduate training there will be no material reduction in the number of interns available for hospital service. However, it is quite likely that some of the civilian hospitals will experience a further shortage in view of the increasing demand for interns in federal hospitals, the reduction of the longer services to one year and the appointment of additional interns in some institutions to compensate for the loss of resident physicians.

Under present conditions it would seem particularly essential that all intern hospitals cooperate in maintaining as uniform a distribution of interns as is practicable in relation to the clinical and educational functions of the various institutions. This will require first of all a reappraisal of the needs of individual hospitals, a task that should be undertaken jointly by the superintendent and the members of the intern committee. Economy in the use of interns can thus be achieved not only from a numerical point of view but also in relation to individual duties and assignments. Obviously the utilization

of an excessive number of interns in any institution will create a corresponding deficiency in the remaining hospitals. In this connection it can be mentioned that the average intern-patient ratio in the hospitals approved for intern training is usually one intern to six hundred annual admissions.

* Internships available annually.

TYPES OF INTERNSHIPS

Three types of internships are approved by the American Medical Association—rotating, mixed and straight. The most common is the rotating service, which provides training in medicine, surgery, pediatrics, obstetrics and their related subspecialties together with experience in laboratory and roentgenologic diagnosis. The mixed internship covers more than one of the clinical specialties but does not include all of the divisions listed. A straight internship is one that provides supervised experience in a single department and may be approved if limited to medicine, surgery, pediatrics, obstetrics, obstetrics-gynecology or pathology.

Of the 732 hospitals currently approved for intern training, 660 offer a full rotating service, 27 have mixed assignments, 18 provide straight internships, 17 have both rotating and straight services, 5 have mixed and straight services, 2 have rotating and mixed services, while 3 hospitals furnish all three types.

Since the intern year is mainly a preparation for general practice and a prerequisite for subsequent training in special fields, it is quite logical that most graduates should prefer a full rotating service so as to gain wide experience in relation to the various aspects of modern medicine. Actually 6,226, or 86.1 per cent, of the 7,228 annual internship appointments are now of the rotating type, while 757, or 10.4 per cent, are straight services and 245, or 3.4 per cent, mixed.

LENGTH OF INTERNSHIPS

Reports from 729 intern hospitals in 1939 showed that 578 had internships of twelve months duration, twenty-six offered services of eighteen months, while 84 listed assignments of twenty-four months or over. Six, however, had other schedules ranging from fourteen to twenty-two months and 35 had internships of varying length as, for example, twelve and eighteen months, twelve and twenty-four months or similar combinations.

A study completed in January 1942 shows that 608 of the approved hospitals are now offering twelve months

internships, 17 have services of eighteen months and 71 are in the two year group. Twenty-five hospitals have both twelve and twenty-four months assignments, whereas 2 have combinations of twelve and eighteen months, 1 twelve and fourteen, 1 eighteen and twenty-four, 1 twelve and twenty-five, and 1 twelve, eighteen and twenty-four. Five other hospitals offer schedules of twenty, twenty-one, twenty-two, thirty and thirty-six months respectively.

Already many of the longer internships have been reduced to one year in conformity with the military needs of the country, while others are changing at the beginning of the new intern year in July. A few apparently will retain the two year plan but will no doubt offer a complete internship during the first twelve months, so that adequate training can be assured to those who may be called to military service at the end of the regular intern year.

NECROPSY PERFORMANCE IN INTERN HOSPITALS

The importance of necropsy performance received early recognition, as evidenced by the request for information concerning necropsies in the hospital surveys of the Council in 1913, 1915 and 1918. Moreover, the

first schedule of Internship Essentials published in 1919 contained a requirement that necropsy facilities be available and that interns obtain experience in making postmortem examinations under the direction of the hospital pathologist. This matter received further emphasis in the revision of the Essentials in 1925 and,

following a special study of hospital necropsy rates, the Council in 1927 decided that after Jan. 1, 1928 no hospital would be approved for intern training that did not obtain necropsies on at least 10 per cent of the patients dying in the institution, this requirement to be increased to 15 per cent after Jan. 1, 1929.

TABLE C.—Necropsy Performance in Approved Intern Hospitals

Below 15.....	329	71	26	7	8	19
Hospitals reporting.....	578	664	732	721	718	727

The results were indeed gratifying, for within one year 586, or 93 per cent, of the approved intern hospitals obtained the required 10 per cent or more of necropsies. Thus only forty-five hospitals failed to meet the minimum requirement in 1928, whereas 222 were below 10 per cent in 1926. Subsequent performance is clearly illustrated in table C. In this the most striking feature is perhaps the rapid decline in the number of hospitals below 15 per cent, while the continuing increase in the higher percentage groups indicates that the hospitals are constantly making every effort to increase their teaching facilities beyond the minimum needs. As a matter of fact the average necropsy rate in the hospitals approved for intern training in 1937 was 34.4 per cent on the basis of 85,050 necropsies and 247,410 deaths, including stillbirths. When stillbirths and coroners' cases not available for teaching were excluded in 1938 the average rate was 37.6 per cent. This was later increased to 37.8 per cent in 1939 and 38.9 per cent in 1940. A slight gain was noted in 1941, when the hospitals approved for intern training reported 211,935 deaths and 82,587 necropsies, indicating an average ratio of 38.97 per cent (see table, page 1066).

In this connection it is of interest to note that the hospitals approved for internships, residencies and fellowships had a total of 250,090 deaths and 96,151 necropsies last year, an average of 38.4 per cent, whereas all other registered hospitals reported 260,068 deaths and 29,489 postmortem examinations, or 11.3 per cent.

DENTAL INTERNSHIPS

The Council on Medical Education and Hospitals does not attempt to exercise supervision over dental internships. However, it may be of interest to note that 152 of the 732 hospitals approved by the American Medical Association for intern and residency training are currently employing 275 dental interns. Further reference to individual hospitals offering dental internships will be included in the next revision of the approved intern list of the Council.

BLOOD AND PLASMA BANKS IN APPROVED HOSPITALS

In January 1942 a survey was made of the facilities for blood and plasma banks in the hospitals approved for internships, residencies and fellowships. Of the 1,070 approved hospitals 462, or 43.2 per cent, reported that such facilities were either in operation or in the process of being established. Some of these institutions also act as manufacturing and distributing centers to

supply blood, plasma or serum to other hospitals in the vicinity. The reports also indicated that many hospitals have commercial products on hand to meet emergency needs.

Reference to table D will show that 206 hospitals maintain both blood and plasma banks, with 17 others in the process of development. In addition there are 171 hospitals operating plasma banks and 33 separate institutions with blood banks. Furthermore it was reported that nine additional blood banks are being established as well as twenty-six plasma banks. Forty-eight other hospitals stated that facilities are available without specifying in what particular form.

RESIDENCIES AND FELLOWSHIPS

Of the 6,358 hospitals now registered by the American Medical Association, 632 have assumed an educational function in accordance with the standards set forth in the Essentials of Approved Residencies and Fellowships. Included in this group are 294 of the 732 institutions which are approved for intern training. From reports received in January 1942 it is apparent

that these hospitals are offering 5,656 internships exclusive of affiliate services, 2,664 approved residencies, 1,887 assistant residencies and 742 fellowships as well as 601 general and other services not yet certified by the Council. Actually, however, there were 5,236 interns on duty at the time of reporting and 5,756

residents, assistant residents and fellows. In this connection it may be of interest to note that in the 1,070 hospitals approved for internships, residencies or both there are now 7,219 interns employed, 2,036 assistant residents, 3,311 residents and 802 fellows.

The number and types of approved residencies are listed in table E. These are usually of one, two or three years duration but may in some instances extend over a period of five or six years. Detailed information concerning individual residencies is published annually in the Educational Number of THE JOURNAL, particularly with reference to the number of patients treated in each service, outpatient visits, deaths, necropsies, the number of residents, assistant residents and fellows employed and the initial monthly stipend.

The inspection and evaluation of residencies in specialties have been carried out by the Council since the publication of the first approved list in 1927. Prior to that time the special hospital assignments were included in the internship list which was officially established in 1914. The procedure involved in the investigation and appraisal of residencies and fellowships was outlined in THE JOURNAL, March 26, 1938, page 978. Subsequently a statement was included in the March 30, 1940 issue, pages 1172-1173, describing the program of collaboration entered into by the Council and the specialty boards in order to secure uniformity in the evaluation of educational opportunities and eliminate unnecessary effort in the inspection of individual hospital assignments. This cooperative plan not only is utilized in connection with the new applications for residency approval but is proving equally helpful in the reappraisal of services certified by the Council prior to the establishment of the American boards.

TABLE E—Classification of Approved Residencies and Fellowships—1942

Totals	2,664	1,887	742	5,293	*

* Number of hospitals approved for Residencies and Fellowships, 637.

In 1914 there were 428 special internships available in 95 hospitals. These remained practically at the same level during the succeeding ten years, as they totaled only 595 in 1924 although the number of hospitals had increased to 150. The formation of a separate residency list in 1927 gave needed impetus to the program of specialty training, which has recently culminated in the

establishment of certifying boards in fifteen of the divisions of medicine and surgery. Since that time the opportunities for residency training have actually tripled with the extension of hospital assignments from 1,776 to 5,293 and the number of approved institutions from 278 in 1927 to 632 at the present time.

The rate of growth has been fairly uniform throughout, although considerable acceleration has occurred in recent years in view of the continuing emphasis on specialization and the certifying activities of the American boards. In view of military needs it can be expected that residencies in specialties will be greatly curtailed during the coming year. Efforts are being made, however, by the Council on Medical Education and Hospitals and the Advisory Board for Medical Specialties to develop a plan whereby a certain percentage of recent graduates may be given an opportunity to continue their training beyond the period of a one year internship. To some extent the residency training program will also be maintained through the employment of physicians ineligible for military service who may wish to secure additional hospital experience in the specialties. While it is apparent that much of the residency work in civilian hospitals will necessarily be discontinued one does not hesitate to predict that American hospitals which are already well advanced in the field of graduate training will again be ready to resume their educational function when the present emergency is over.

HOSPITALS REGISTERED BY THE AMERICAN MEDICAL ASSOCIATION

The following list contains the names of 6,358 hospitals, sanatoriums and related institutions that are located in the United States and 248 in Alaska, Canal Zone, Hawaii, Philippines, Puerto Rico and Virgin Islands. The list for each state is presented in two groups: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include infirmaries, nursing homes and other institutions designed to give certain medical and nursing care in an ethical and acceptable manner, without giving a full hospital service.

Registration of hospitals is governed by the Essentials of a Registered Hospital, adopted by the House of Delegates in 1928 and revised in 1939.

Registration is a basic recognition, extended to all the hospitals and related institutions in the following list, concerning which we have no evidence of irregular or unsafe practices. Approval is designation of certain registered institutions by the Council on Medical Education and Hospitals for internships, residencies and fellowships; or by the American College of Surgeons as unconditionally meeting its minimum standards.

KEY TO SYMBOLS AND ABBREVIATIONS

- * Approved for training interns by the Council on Medical Education and Hospitals. List with detailed information is sent on request.

+ Approved for residencies or fellowships. List with detailed information is sent on request.
- ▲ Approved by American College of Surgeons as meeting unconditionally its minimum standards.

◊ School of nursing accredited by state board of nurse examiners.

◉ Affiliated for nurse training on state accredited basis.

† Figures for "average census" and "admissions" are exclusive of newborn infants.

The column headed "Type of Service" tells what diseases are treated in each institution:

Card	Cardiac	ENT	Eye, ear, nose and throat	Iso	Isolation	N&M	Nervous and mental
Chil	Children	Gen	General	Mat	Maternity	Orth	Orthopedic
Cbr	Chronic	Incur	Incurable	MatCh	Maternity and children	SkCa	Skin and cancer
Conv	Convalescent and rest	Indus	Industrial	MeDe	Mentally deficient	TB	Tuberculosis
Drug	Drug and alcoholic	Inst	Institutional	Ment	Mental	Ven	Venereal
Epil	Epileptic						

The column headed "Control" indicates control, or auspices under which the institution is conducted:

GOVERNMENTAL				NONPROFIT ORGANIZATIONS		PROPRIETARY	
Fed	Federal	State		Church		Indiv	Individual
IA	Indian Affairs	City		NPAssn	Nonprofit Association	Part	Partnership
Army	United States Army	County				Corp	Corporation (unrestricted as to profit)
Navy	United States Navy	City-County					
USPHS	United States Public Health Service	CyCo					
Vet	Veterans Administration Facility						

The accompanying list omits additions to hospital facilities that may have been made by certain departments of the Federal Government since the publication of the last previous issue March 15, 1941.

Corrections were made in the list to the time of going to press. Totals of the list, therefore, may vary from totals in Tables 1 and 2 which were necessarily compiled earlier.

SCHOOLS FOR CLINICAL LABORATORY TECHNICIANS

The original survey of 196 schools for clinical laboratory technicians was published in *THE JOURNAL*, Aug. 29, 1936, together with the first list of 96 approved schools. Essentials had been formulated by the Council on Medical Education and Hospitals of the American Medical Association, with the cooperation of the American Society of Clinical Pathologists and ratified by the House of Delegates of the American Medical Association in May 1936.

There are currently 174 such schools on the approved list. The returns from these schools indicate that 917 students were graduated during the year 1941. This represents an increase of 216 graduates as compared with the previous year. In general, the enrolment in these schools is small, only 41 schools having a maximum enrolment of 10 or more students.

One hundred and thirteen of the approved schools report that all their graduates find positions locally, and 61 schools report that their graduates are somewhat in excess of the local needs. The statistics in general suggest that the present demand for technicians undoubtedly exceeds the number that are being graduated each year. During the calendar year 1941 there was a total of 1,084 students in the approved schools. The maximum number of students that could be accommodated in the present approved schools is 1,254.

During the past year changes have been made in the prerequisites for admission in the Essentials of an Acceptable School for Clinical Laboratory Technicians, as follows:

(a) Two years of college work, including chemistry and biology, from an accredited college or university. After Jan. 1, 1943 this requirement shall read: Two years of college work, including general chemistry, quantitative chemistry and biology from an accredited college or university. Bacteriology may be substituted for biology. Organic chemistry and physics are highly recommended.

(b) Graduation from a school of nursing recognized by the state board of nurse examiners, and in addition college chemistry.

After Jan. 1, 1943 requirements for nurses shall include one year of college work, 30 semester hours (45 quarter hours), including courses in chemistry and biology.

The majority of the approved schools require for admission two years of preliminary college training,

while approximately one fourth of the schools require a degree from an acceptable college. A few schools accept nurse training in lieu of a portion of the required college work. Although two of the schools affiliated with colleges are apparently admitting students directly from high school, the required courses extend over four or five years and include all the prerequisites for admission to approved schools.

The length of the course within the schools themselves is twelve months in 77 per cent of the schools. Other schools have programs ranging from fifteen to twenty-four months duration.

It is now possible to indicate the number of approved schools which have definite affiliations with colleges and universities. Fifty-eight schools report that they have entered into such affiliations as a result of which students receiving their prerequisite training in a university or college receive their hospital training in a designated institution. Forty-four colleges having such affiliations are granting college credit for the time spent in the school for the training of laboratory technicians. This credit ranges from one-half semester to two years, with the majority reporting one complete year of college credit, given to the students who are properly enrolled on completion of their course as a laboratory technician.

Approximately 48 per cent of the schools charge no tuition. Some affiliated with universities charge the usual university fees. The tuition in the other schools varies from \$25 to \$300. Only approximately 15 per cent of all schools have a tuition charge of more than \$150.

There is definite evidence of an increasing demand for laboratory technicians as well as an increasing interest in this field on the part of college women.

Correspondence regarding schools for the training of clinical laboratory technicians should be addressed to the office of the Council on Medical Education and Hospitals. Graduates of approved schools desiring registration should communicate with the Board of Registry of Medical Technologists, Ball Memorial Hospital, Muncie, Ind.

NOTE: The list of approved schools appears on pages 1138-1142.

SCHOOLS OF OCCUPATIONAL THERAPY

At the Milwaukee Session of the House of Delegates of the American Medical Association in 1933 a resolution was introduced that some plans be effected for the establishment of standards, ratings and inspections of training schools in occupational therapy. This program was referred to the Council on Medical Education and Hospitals, and all of the 13 existing schools were surveyed. Essentials of an Acceptable School of Occupational Therapy were ratified by the House of Delegates of the American Medical Association at the Atlantic City session in 1935, such standards to become effective on Jan. 1, 1939. A report of the Council on Medical Education and Hospitals to the House of Delegates in 1936 contained the names of 4 schools which had already met these standards. There are currently 6 schools on the approved list.

The occupational therapist is trained to work under the direction of a physician and should be capable of

suggesting programs designed to recreate specific functions or to encourage restoration of impaired functions.

The 1941 questionnaires returned by the 6 schools currently approved indicate that 118 students were graduated from these schools. There are 162 additional students who are expected to graduate in 1942.

Prerequisites for enrolment in an approved occupational therapy school include one year of general college, while 1 school requires two years of college work. Although 4 schools admit students directly from high school, the required courses extend over a period of five years and include all the prerequisites for admission to approved schools of occupational therapy. The courses based on one or two years of preliminary college work operate on a twenty-seven month or three year program. All schools grant a diploma when the student graduates, while 4 offer a bachelor's degree in occupa-

APPROVED SCHOOLS OF OCCUPATIONAL THERAPY

Name and Location	Director	College or University Affiliation	Duration	Enrolment Starts	Entrance Requirements	Tuition	Certificate, Diploma, Degree	Total Graduates in 1941
Boston School of Occupational Therapy, 7 Harcourt St., Boston	Mrs. John A. Greene	None	30 consecutive mos.	September	1 yr. coll.	\$300 yr.	Diploma	26
Kalamazoo State Hospital School of Occupational Therapy, Kalamazoo, Mich.	Miss Marion R. Spear, B.S.	Western Michigan College of Education, Kalamazoo	27 consecutive mos. for diploma and 5 yrs. for degree course	April and October	1 yr. coll. for diploma course; high sch. grad. for degree course	\$70 yr. at Western Michigan College	Diploma or B. S. Degree	7
St. Louis School of Occupational and Recreational Therapy, 4567 Scott Avenue, St. Louis	Miss Geraldine R. Lermitt, A.B.	Washington University, St. Louis	3 yrs. for diploma and 5 yrs. for degree course	September	2 yrs. coll. for diploma course; high sch. grad. for degree course	\$325 yr.	Diploma or B. S. Degree	10
Philadelphia School of Occupational Therapy, 419 South 19th Street, Philadelphia	Miss Helen S. Willard, A.B.	University of Pennsylvania, Philadelphia	3 yrs. for diploma and 5 yrs. for degree course	September	1 yr. coll. for diploma course; high sch. grad. for degree course	\$600 for 3 yr. course; candidates for degree pay univ. fees	Diploma or B. S. Degree	26
Milwaukee-Downer College, Department of Occupational Therapy, 2512 East Hartford Avenue, Milwaukee	Miss Henrietta McNary	Milwaukee-Downer College	3 yrs. for diploma and 5 yrs. for degree course	September	1 yr. coll. for diploma course; high sch. grad. for degree course	\$250 yr. for diploma course; \$230 yr. for degree course	Diploma or B. S. Degree	13
University of Toronto, Department of University Extension, Toronto, Ont., Canada	Mr. W. J. Dunlop, Director of University Extension and Publicity; Miss Helen F. LeVesconte, Supervisor of Course	University of Toronto	30 consecutive mos.	September	1 yr. coll.	\$175 yr.	Diploma	36

tional therapy. Only 1 school admits male students to its regular classes.

The annual tuition varies from \$70 to \$325.

Correspondence regarding schools training occupational therapy technicians should be addressed to the office of the Council on Medical Education and Hospitals. Graduates of approved schools desiring registration should communicate with the American Occupational Therapy Association, 175 Fifth Avenue, New York City.

SCHOOLS FOR PHYSICAL THERAPY TECHNICIANS

The House of Delegates of the American Medical Association in 1934 requested that some plan be effected for the establishment of standards, ratings and inspections of training schools for physical therapy technicians. The Council on Medical Education and Hospitals assumed responsibility for this program and by 1936 had completed a survey of these schools. Certain minimum standards were formulated. These were presented to the House of Delegates of the American Medical Association and were ratified in May 1936. The first published list of 13 approved schools for physical therapy technicians appeared in THE JOURNAL in August 1936. At present there are 16 approved schools.

In 1941, to meet the emergency requirements of the Army, a concentrated curriculum involving intensive courses in the basic principles of physical therapy was instituted by nine schools. Such courses with the approval of the Council include a minimum of experience consisting of eight hundred hours of theory and laboratory work as well as two hundred hours of practice within a six months period. Additional schools are considering the adoption of similar programs. The shortening of the training program occurs in the clinical practice. Graduates of such courses are not considered qualified technicians but are eligible for the U. S. Civil Service rating of Apprentice Physiotherapy Aide and therefore are available for service in the armed forces. The schools offering these concentrated courses are certifying the students' training in the basic sciences and grant a certificate after an additional six months of satisfactory experience and training in the armed forces. After receiving this certificate the student is eligible for promotion to the rank of Physiotherapy Aide by the U. S. Civil Service Commission and for registration by the American Registry of Physical Therapy Technicians.

The 1941 questionnaires returned by the sixteen schools currently approved indicate that 168 students can be trained in the regular courses, while 400 can be trained in the emergency courses. There was a total of 238 graduates last year, including only 84 students who completed the concentrated six months curriculum.

The common experience of the schools charging tuition is that they cannot obtain enough students to fill their classes in spite of the large number of applications. Aside from the schools charging no tuition, the fees vary from \$200 to \$547 for the regular course and from \$200 to \$286 for the emergency course.

The acute shortage of physical therapy aides reported by the Central Physical Therapy Board of the Office of the Surgeon General of the U. S. Army has been referred to the Council and is being studied by it. The available facilities for training 400 students in the emergency courses in addition to the facilities for the training of 168 students in the regular courses would appear to indicate that there is now ample provision for the training of students if a sufficient number of individuals can be interested in undertaking such training.

Correspondence regarding schools for physical therapy technicians should be addressed to the Council on Medical Education and Hospitals. Graduates of approved schools desiring registration should communicate with the American Registry of Physical Therapy Technicians, 30 North Michigan Avenue, Chicago.

NOTES

- Male students are admitted.
- Students from other than affiliated colleges and universities are also accepted.
- Students from other than affiliated college must have degree.

- South Bend Medical Laboratory serves as the pathology department for Epworth Hospital and St. Joseph's Hospital, South Bend.
- Bender Hygienic Laboratory serves as the pathology department for the following hospitals: Anthony N. Brady Maternity Hospital, Memorial Hospital and St. Peter's Hospital, Albany; Memorial

Hospital of Greene County, Catskill; Hudson City Hospital, Hudson, and Troy Hospital, Troy.
 4. College graduates and graduate nurses with two years of college are also admitted.
 5. Includes training in x-ray.

SATURDAY, MARCH 28, 1942

INTERNSHIPS, RESIDENCIES AND FELLOWSHIPS

The annual report of the Council on Medical Education and Hospitals with reference to internships and residencies in specialties appears in this issue of THE JOURNAL. Though the records are based on reports for the calendar year 1941, all hospitals approved by the Council as of March 1, 1942 are included. These total 1,070, of which 438 are approved for internships only, 338 for residencies and 294 for both interns and resident physicians. The 732 hospitals accredited for intern training offer 7,228 internship appointments annually, whereas the 632 residency hospitals provide 2,664 approved residencies, 1,887 assistant residencies and 742 fellowships, as well as 601 general and other services not yet certified by the Council. These hospitals have a significant role in medical education, illustrated by the fact that they are currently engaged in the training of 7,219 interns and 5,756 residents, assistant residents and fellows. This represents the equivalent of two and a half annual graduating classes of all approved medical schools in the United States.

The undergraduate medical curriculum does not offer sufficient training to meet the medical needs of a community. Recent graduates must therefore receive further experience in clinical practice under the guidance of a competent hospital staff. The internship fulfills this purpose and serves to complete the preparation for general practice. It bears an equally important relationship to the graduate field, where it constitutes an essential prerequisite for residency, fellowship and other specialty training that may lead to certification by the American specialty boards. In the broadest sense the internship is part of the fundamental training essential to a career in medicine. The internship provides basic preparation not only for general and special practice but also for administrative medicine, educational pursuits, research and other activities which require a medical background. The preservation of the internship is therefore essential to the maintenance of adequate standards of medical practice. This is fully recognized by the United States Army, the United

States Navy and the Selective Service, which have made provisions whereby interns, medical students and even premedical students who have matriculated in medical schools may secure deferment from active military service until they have completed their undergraduate studies and one year of internship.

According to present indications the number of interns available for hospital service will not be lessened. Indeed, it may be increased because of the accelerated program of medical education adopted by most approved medical schools, which involves the graduation of a class every nine months. The long term internships are now generally being reduced to twelve months in accordance with military needs, but necessity has not been apparent for any further reduction below this point. Hospitals may need to readjust their arrangements for the internship, however, to provide for the appointment of interns at such times as will coincide with the new periods of graduation. The integration of one year internships with the accelerated curriculum of the medical schools presents many difficulties.

Under the present circumstances, hospitals should cooperate to maintain a uniform and equitable distribution of interns in relation to the clinical and educational requirements of the various institutions. Every hospital, therefore, should reexamine its intern program and carefully limit the number of appointments to actual minimum needs.

Though provision has been made for the deferment of medical students and interns, a similar plan has not been developed to provide for the training of young physicians beyond the period of a one year internship. Residencies in specialties will no doubt be greatly curtailed during the present emergency, since the majority of medical graduates will probably be called to military service immediately on completion of the regular intern year. Efforts are being made, however, to maintain the present resident structure at least on a skeleton basis so that the approved hospitals may be able to resume this educational function without delay as soon as conditions again become favorable.

Since the further education of a certain number of physicians is vital to the future welfare of the country, the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association have appointed a committee whose chief purpose is to formulate plans whereby a percentage of interns may be given an opportunity to continue their training in the special fields of medicine.

Efforts are being made by all the agencies concerned to prevent any depreciation in the standards of medical education, hospital service and medical care during the war. The indications are that the needs of the Army, the Navy, public health and the civilian population can be met by scientific planning and complete cooperation without any deterioration in the quality of medical education and medical service.

HOSPITAL SERVICE IN THE UNITED STATES

The statistics published in this issue of *THE JOURNAL* show that there are available in the registered hospitals of the United States 98,136 more hospital beds than were available in 1941. This increase in bed capacity during the past year has been the equivalent of one additional 269 bed hospital for every day of the year, Sundays and holidays included.

The annual census of the registered hospitals just completed by the Council on Medical Education and Hospitals shows a total capacity of 1,324,381 beds and 66,163 bassinets, as of Dec. 31, 1941. There were 11,596,188 patients admitted to these hospitals, 5,201,650 of whom underwent surgical operation.

The number of births in the reporting hospitals was 1,404,940, an increase of 190,448 over the preceding year.

Moreover, the hospitals of this country are functioning more efficiently and more effectively. The average length of stay in general hospitals has been reduced from fourteen days in 1935 to twelve days in 1941. Based on this reduction of two days in the average length of stay, and estimating conservatively the minimum cost per patient day at \$4, the cost of hospitalization for the 10,646,947 patients admitted to the general hospitals of the country was \$85,175,576 less than it would have been in 1935.

The inclusion of statistics with regard to certain nonmedical personnel not previously published emphasizes the enormous problem involved in rendering efficient hospital service to the public.

The hospitals throughout the country have individually and in cooperation with other agencies been formulating programs to meet such emergencies as may arise in connection with the war.

The data submitted suggest that the hospitals of this country have never been in better position to meet successfully such demands as may be made.

THE RECORD KEEPING OF EXEMPT NARCOTIC PREPARATIONS

Physicians who dispense attenuated narcotic preparations, which are exempted from the Harrison Narcotic Act by section 6 of that act, need not keep a record of such drugs if dispensed for a legitimate therapeutic purpose to a patient on whom the physician is in personal attendance. In a recent decision,¹ the United States Supreme Court clarified an apparent ambiguity in the Harrison Narcotic Act. That act, as far as the more potent narcotic drugs are concerned, excuses a physician from keeping records when he dispenses narcotic drugs to patients on whom he is in personal attendance. In the case of the less potent prepara-

tions, however, section 6, after describing the so-called exempt preparations, imposes a duty of record keeping on "any manufacturer, producer, compounder, or vendor (including dispensing physicians) of the preparations and remedies" mentioned in the section. The use of the designation "dispensing physicians" has been construed to impose on a physician who dispenses any of the exempt narcotic preparations to a patient the duty of keeping a record of the transaction. Such an intent on the part of the Congress has been difficult to justify in view of the fact that record keeping is not required of physicians in the case of the potent narcotic drugs.

The present case arose in Hawaii. The defendant was a licensed physician who was prosecuted for failure to keep records of paregoric and certain other exempt preparations which he dispensed to patients. A conviction followed, and the case eventually reached the United States Supreme Court. Justice Murphy, speaking for the court, said that Congress by using the words "dispensing physicians" in connection with the proviso relating to the keeping of records of exempt preparations clearly meant to exclude physicians administering to patients whom they personally attend. In the words of the court:

That not all physicians are required to keep records is manifest from the use of the qualifying adjective "dispensing." And, the physician must be one who manufactures, produces, compounds, or vends, or possibly only one who vends if the parenthetical phrase applies only to "vendor," the drugs. These are not appropriate words to describe the function of a physician who administers exempt preparations to patients whom he personally attends. . . .

The legislative history of the second proviso of section 6 supports the view that the words "dispensing physicians" were intended to apply only to physicians acting as dealers in the sale of drugs.

Justice Murphy called attention to the fact that Congress unequivocally exempted physicians from record keeping where in personal attendance on patients in connection with the use of the more potent narcotics and stated that it was difficult to perceive "why a different requirement should obtain when a physician, under similar circumstances, administers preparations containing only a limited amount of narcotics, such as the paregoric, cough syrup, etc., involved in this case."

One unusual feature of this case was that the government, when the case came before the Supreme Court, agreed with the position taken by the physician and consented to a reversal of the judgment of conviction. In a Memorandum for the United States, filed in the Supreme Court, the attorneys for the government frankly admitted that the provision in section 6 relating to record keeping should not apply to a physician who administers exempt narcotics solely to patients upon whom he personally attends. The language of the requirement, it was pointed out in the memorandum,

imposes the record keeping requirement upon "any manufacturer, producer, compounder, or vendor (including dispensing physicians)." The words "dispensing physicians" in this con-

1. *Peter Young, alias Young Lup, v. United States*, 62 S. Ct. 510, decided Feb. 2, 1942.

nection may be reasonably interpreted as applying only to physicians dispensing to persons other than patients upon whom they personally attend, e. g., country doctors who may act as druggists, physicians who engage in the manufacture and general distribution of patent medicines. An interpretation of the proviso which limits it to this type of situation makes it harmonize with section 2(a) where, in dealing with true narcotics, Congress unequivocally stated its intention to exempt physicians from record keeping when in personal attendance upon patients.

Apparently the Bureau of Narcotics knew nothing of the proceeding that had been instituted against the defendant physician until after the judgment of conviction had been entered. Furthermore, the Acting General Counsel of the Treasury Department, in a letter to the United States Solicitor General in connection with this case, under date of Nov. 29, 1941, expressed the position of the Department of the Treasury, under which the Bureau of Narcotics functions, as in general accord with the construction placed by the defendant physician on the record keeping requirement as far as it relates to "dispensing physicians."

Current Comment

PHYSICIANS FOR THE AIR FORCE

From the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, as indicated elsewhere in this issue, comes a request for physicians in the air force. The Army wants specifically for this purpose two thousand five hundred physicians, who will be commissioned by July 1; it will need six hundred additional physicians each month for the remainder of the calendar year. This alone is a total of six thousand one hundred physicians. Most of those required are to be under 37 years of age. Among the ones certified as specialists in surgery, ophthalmology and neuropsychiatry, more than a thousand are needed between the ages of 37 and 45. The place of the air force in the winning of the war is already clear to every intelligent person. The need is immediate. If you feel you can qualify, write to the Air Surgeon, Army Air Force, Washington, D. C., giving the information that is specified. Everything possible will be done to facilitate immediate commissioning of the applicant in a rank suitable to the place he will occupy.

MEDICAL-PHARMACEUTICAL CONFERENCE

By arrangement of the Board of Trustees of the American Medical Association, representatives of the Council on Pharmacy and Chemistry met on March 8 with a similar committee from the American Pharmaceutical Association to arrange a medical-pharmaceutical conference. The representatives for medicine were Drs. Harold N. Cole, Morris Fishbein, Theodore G. Klumpp, Austin E. Smith and Torald Sollmann. The representatives for pharmacy were Dean B. V. Christensen, Mr. Charles H. Evans, Dr. E. F. Kelly and Dean Robert C. Wilson. It had previ-

ously been decided that the conference should be held concurrently with the special meeting of the U. S. Pharmacopeial Convention, which is to take place in Cleveland on April 7. Thus the function of this informal meeting between representatives of medicine and pharmacy was to arrange a program for the open session, which will be held on April 6 at the Statler Hotel. The program evolved follows:

2 p. m. DEAN TORALD SOLLMANN presiding.

1. Evolution of the Apothecary. HOWARD DITTRICK.
2. Trends of Pharmaceutical Practice. E. F. KELLY.
3. Objectives of the Program of Pharmaceutical Education. DEAN ROBERT C. WILSON.

6:30 p. m. Dinner. DEAN B. V. CHRISTENSEN presiding.

Address: Status of Medicine and Pharmacy In the War and After. MORRIS FISHBEIN.

Discussion of the papers will be opened by speakers prominent in their respective fields as related to medicine and pharmacy. General open discussion is limited to two minutes to each contributor, who may speak but once. Reservations for the dinner may be made with, or tickets procured from, the Committee on Arrangements on the day of the conference. This committee consists of Dean Robert C. Wilson, School of Pharmacy, Georgia, Dr. Austin E. Smith, Acting Secretary of the Council on Pharmacy and Chemistry, and the local Cleveland representative, whose name will be posted on the conference room bulletin board. The conference and dinner (business dress) will be held in the Lattice Room. It is hoped that this conference will be attended not only by those who plan to attend the U. S. Pharmacopeial Convention but by all members of the pharmacal and medical professions who are interested in any aspect of the program.

AMPUTATIONS AND PROSTHESES

The correct site of election for amputation, to assure a serviceable and functional stump, and the mechanics of the prosthesis are among many other subjects considered in a recent publication of the American Medical Association, the "Handbook on Amputations,"¹ sponsored by the Council on Physical Therapy and its group of Consultants on Artificial Limbs. Specialists in the surgery of amputation and experienced artificial limb manufacturers cooperated in this work. The psychology of the patient who has lost a leg or an arm is given special consideration. Amputations in diabetes mellitus and peripheral vascular diseases are described along with postoperative care and physical therapy of the stump. An interesting innovation is the use of ice as a substitute for chemical anesthesia. In emergency, cracked melting ice and a tourniquet may be used in the amputation of a leg or an arm without pain to the patient. Amputations and their associated injuries are grim reminders of the aftermath of war. The Council has rendered a service to medicine by compiling this timely volume.

1. Handbook on Amputations, Chicago, American Medical Association, 1942, price 75 cents.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

WAIVER OF PHYSICAL DEFECTS FOR LIMITED SERVICE OFFICERS

On January 30 the following communication was sent to surgeons in all corps areas and departments except the Philippine Department and to the commanding officers of all general hospitals except Sternberg General Hospital in Manila.

1. In order that the provisions of AG 210.31 (12-19-41)RP-A, Jan. 7, 1942, subject: Waiving of physical defects for limited service officers of the supply arms and services may be carried out in a uniform manner, the following policies of this office concerning recommendations for waiver for limited service are announced:

(a) Considered acceptable for limited service:

(1) Overweight to 25 per cent above average weight for age and height, and underweight to 15 per cent below ideal weight, provided chest x-ray examination is negative for pulmonary pathologic change and other chronic disease is carefully excluded.

(2) Vision 20/400 in each eye corrected with glasses in possession of the examinee to 20/20 in one eye and to at least 20/40 in the other, provided no organic disease of either eye exists.

(3) Blindness, or vision below 20/400, in one eye with vision 20/100 corrected with glasses in possession of the examinee to 20/20 in the other, provided there is no organic disease in the better eye and no history of cataract or other disease in the more defective eye which might be expected to involve the better one, and provided that, in case of ophthalmosteres, the individual is fitted with a satisfactory prosthesis.

(4) Complete color blindness.

(5) Hearing 5/20 in each ear for low conversational voice, or complete deafness in one ear with hearing 10/20 or better in the other, provided the defect is not due to active inflammatory disease and is stationary in character.

(6) Chronic otitis media, inactive, with perforation of membrana tympani, provided there is a trustworthy history of freedom from activity for the preceding five years.

(7) Old fracture of the spine or pelvic bones which has healed without marked deformity, provided there is a trustworthy history of freedom from symptoms during the preceding two years.

(8) Loss of one hand, forearm, or lower extremity below junction of the middle and lower thirds of the thigh, provided the lost member is replaced with a satisfactory prosthesis.

(9) Pes planus, pes cavus or talipes equinus, provided the condition is asymptomatic and does not interfere with normal locomotion.

(10) History of osteomyelitis following fracture, provided x-ray examination indicates complete healing and the condition has been asymptomatic for the preceding five years.

(11) Joints fixed or limited in motion, provided the condition is the result of injury and is nonsymptomatic.

(12) History of excision of torn or detached semilunar cartilage of knee joint, provided there is normal stability of the joint and a period of one year with complete freedom from symptoms has elapsed since the operation.

(13) Residuals of anterior poliomyelitis, without marked deformity or loss of function, originating two years or more prior to examination.

(14) Varicose veins, moderate, without edema or discoloration of skin.

(15) History of gastric or duodenal ulcer, provided there is a trustworthy history of freedom from activity during the preceding five years and provided a gastrointestinal roentgenogram at the time of examination is negative.

(16) Incomplete inguinal hernia.

(17) Small asymptomatic congenital umbilical hernia.

(18) Absence of one kidney, provided its removal has been necessitated by other than tuberculosis or malignancy and the other kidney is normal.

(b) Considered unacceptable for any service:

(1) History of malignant disease within preceding five years.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

Information from Major Sam F. Seeley, Executive Officer of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, 601 Pennsylvania Avenue, Washington, D. C., states that a request has just been received by that office from the Army Air Force for two thousand five hundred physicians to be commissioned by July 1 and for six hundred physicians to be commissioned each month thereafter for the period of 1942. The total is six thousand one hundred physicians needed this year to provide adequate medical care for the Air Force. The place of the Air Force in the winning of the war is already apparent to every one.

QUALIFICATIONS

Eighty per cent of the physicians to be commissioned must be under 37 years of age. The remaining 20 per cent may be between the ages of 37 and 45 years. Those in the older age group must be qualified by certification as specialists preferably in the fields of surgery, ophthalmology and neuropsychiatry.

The letter of application should state the age of the applicant and the school of graduation and should indicate that he believes himself qualified physically and professionally for a commission.

All names are cleared through the Procurement and Assignment Service.

The letter, requesting application forms, should be sent to the Air Surgeon, Army Air Force, Washington, D. C.

(2) Active tuberculosis of any organ and inactive pulmonary tuberculosis except as described in paragraph 2a.

(3) Syphilis, except adequately treated syphilis as described in paragraph 2b.

(4) Old fracture of the skull with bony defect greater than 2 cm. in longest diameter or with history of accompanying mental or neurologic complications.

(5) Instability of any of the major joints.

(6) History of metastatic osteomyelitis with prolonged or recurrent drainage, regardless of duration.

(7) Arthritis of the atrophic (rheumatoid) type.

(8) Any cardiovascular condition which disqualifies for general military service.

(9) History of gastroenterostomy, gastric resection, intestinal anastomosis or operation for intestinal obstruction.

(10) History of prostatectomy or transurethral resection of the prostate, or of prostatic hypertrophy of any degree.

(11) Chronic endocrine disease except mild hypothyroidism or mild Froehlich's syndrome.

(12) Diabetes mellitus of any degree or renal glycosuria.

(13) History of any psychosis.

(14) History of severe psychoneurosis at any time, or psychoneurosis of any degree if it has been recurrent or has shown symptoms within the preceding five years.

2. The following may be recommended for general military service with waiver:

(a) Individuals with minimal inactive lesions of primary or reinfection type pulmonary tuberculosis. These lesions may consist of:

(1) Calcified residues of lesions of the intrathoracic lymph nodes, provided none of these exceed an arbitrary limit of 1.5 cm. in diameter and the total number does not exceed five.

(2) Calcified lesions of the pulmonary parenchyma, provided the total number does not exceed ten, one of which may equal but not exceed 1 cm. in diameter, but none of the remainder may exceed 0.5 cm. in diameter.

(NOTE.—The lesions described in (1) and (2) should appear sharply circumscribed, homogeneous and dense. Measurements refer to standard 14 by 17 inch direct projection roentgenograms.)

(3) Small fibrotic parenchymal lesions represented in the roentgenogram as sharply demarcated strandlike or well defined small nodular shadows not exceeding a total area of 5 sq. cm., provided acceptance is deferred until subsequent examination demonstrates that the lesions are stationary and are not likely to be reactivated. The minimum period of time to determine this is six months. It must be recognized that either progression or regression of the lesions indicates activity.

(b) Individuals with confirmed positive serologic tests for syphilis with no clinical evidence of the disease, with convincing histories of a trustworthy diagnosis of syphilis, or with reliable histories of treatment for the disease on serologic or clinical grounds; provided:

(1) That a negative spinal fluid since infection and treatment has been reported from a trustworthy source;

(2) That, in infections estimated to be of less than four years' duration, at least thirty to forty arsenical and forty to sixty insoluble bismuth injections or their equivalent, with a minimum total of seventy-five injections, have been given, with approxi-

mate continuity (no rest periods or lapses) during the first thirty weeks of treatment; and

(3) That, except as further qualified, in infections estimated to be over four years' duration, at least twenty arsenical injections and forty to sixty insoluble bismuth injections or their equivalent, with a minimum total of sixty injections, have been given in alternating courses; rest periods between consecutive courses not exceeding eight weeks being allowable.

In infections of unknown duration it shall be presumed for classification purposes that those of individuals under 26 years of age are of less than four years' duration, and over 26 years, of more than four years' duration.

(NOTE.—For the determination of treatment, the signed statement of acceptable treatment sources administering it, with total number of doses of each drug and approximate calendar dates of administration and available laboratory and clinical data, shall be required as evidence.)

(c) Overweight to 20 per cent above average weight for age and height, and underweight to 12.5 per cent below ideal weight, provided a chest roentgenogram is negative for pulmonary pathologic changes and other chronic disease is carefully excluded.

(d) Insufficient incisor or masticating teeth, provided the mouth is free from extensive infectious processes and the examinee is wearing satisfactory dentures.

(e) Pilonidal cyst or sinus, provided there is no palpable tumor mass, no evidence of purulent or serous discharge, and no history of previous discharge or inflammation.

(f) History of healed fracture with bone plates, screws or wires used for fixation of fragments still in situ, provided x-ray examination shows no evidence of osteomyelitis and no rarefaction of bone contiguous to the fixative materials; that such fixative materials are not so located that they will be subjected to pressure from military clothing or equipment, and that one year has elapsed since their application.

(g) History of operation or of injection treatment for inguinal or small ventral hernia, provided examination three months or more following operation, or following the last injection, shows a satisfactory result.

(h) History of unilateral renal calculus, provided the condition has been asymptomatic for the preceding three years, urine examination is negative, and roentgenologic examination (flat plate) of both kidneys is negative.

(i) Absence of the spleen, provided its removal has been necessitated by a crushing injury.

(j) History of cholecystectomy, provided the condition has been asymptomatic for the preceding two years.

3. The action of the reviewing medical authority should indicate on the Report of Physical Examination, W. D., A. G. O. Form No. 63, that cognizance has been taken of any defects which do not meet the standards set forth in AR 40-105, but for which waiver is recommended by a notation as follows:

"Recommend acceptance for general military service with waiver of (here record the defect or defects)," or

"Recommend acceptance for limited service only with waiver of (here record the defect or defects)."

By order of the Surgeon General:

JOHN A. ROGERS,
Lieutenant Colonel, Medical Corps,
Executive Officer.

OFFICE OF CIVILIAN DEFENSE WILL AID ESTABLISHMENT OF BLOOD AND PLASMA BANKS

Hospitals in communities which are exposed to war hazards may receive assistance in the establishment of a blood and plasma bank through funds available to the United States Public Health Service. These will be administered by it through the Medical Division of the United States Office of Civilian Defense. In addition to providing whole blood or liquid plasma for the current needs of hospitals, these blood banks as well as others already in operation are to accumulate a reserve supply of plasma for civilian casualties caused by enemy action. Technical and bacteriologic safeguards are to be observed as recommended

by the Subcommittee on Blood Substitutes of the Division of Medical Sciences of the National Research Council. At the request of the Office of Civilian Defense, a technical handbook on blood and plasma banks has been prepared by this committee, which will be distributed by the Office of Civilian Defense to hospitals.

Following the advice of the committee of the National Research Council, financial and technical assistance will be provided only to three hundred hospitals of two hundred or more beds approved by the American College of Surgeons and the

Hospital Register of the American Medical Association. These hospitals will agree to maintain required technical standards and to accumulate a surplus of liquid or frozen plasma amounting to one unit per bed within three months. Grants will be made only for the purchase of essential equipment if obtainable locally and for sufficient technical assistance to initiate the project. Hospitals will thereafter be expected to continue to maintain the blood and plasma bank to meet their daily needs as well as the plasma reserve for civilian casualties.

Technical guidance has also been made available through the appointment of Dr. John B. Alsever of Syracuse, N. Y., by the Surgeon General of the U. S. Public Health Service, and his assignment to the medical division of the Office of Civilian Defense as technical director of its blood and plasma service. Dr. Alsever will be assisted by regional technical consultants

in various parts of the country, whose consulting services will be made available to hospitals in their area.

As a further safeguard for the civilian population, the United States Public Health Service is providing for the production of 50,000 units of dried plasma or human albumin in laboratories approved for the manufacture of biologic products by the National Institute of Health. The American Red Cross has agreed to collect the blood for this purpose without interference with its blood collecting services for the armed forces. This second reserve of dried plasma will be distributed to Office of Civilian Defense depots located in various parts of the country. It will be made available by the medical division of the Office of Civilian Defense to stricken communities for their casualties whenever their own local stores of liquid or frozen plasma are in danger of being depleted.

ORGANIZATION SECTION

OFFICIAL NOTES

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Report of a Meeting of the Council on Medical Education and Hospitals, held in Chicago, Feb. 15, 1942

RESOLUTION ON THE DEATH OF DR. W. D. CUTTER

The members of the Council, in expressing their deep regret in the loss of Dr. William D. Cutter, Secretary of the Council on Medical Education and Hospitals from Dec. 1, 1931 until his death on Jan. 22, 1942, passed the following resolution by unanimous action:

In the demise of William D. Cutter, M.D., the Council on Medical Education and Hospitals lost a valuable secretary and organized medicine a true friend.

Dr. Cutter's services to scientific teaching, his life-time devotion to medical education, his unwavering faith in the destiny of American medicine and his career as a medical educator made a splendid contribution to the work of the Council.

His character and ideals, happily combined with high ethical values, will long be remembered and cherished.

The members of the Council desire to record their appreciation and gratitude for his splendid services and to express their great personal loss in his death.

The Council sponsored a meeting in the Assembly Hall of the Association headquarters on Monday evening, February 16, to honor the memory of Dr. Cutter. The speakers were Dr. Ray Lyman Wilbur, Stanford University, Calif., whose address was entitled "Cutter, the Medical Administrator"; Dr. Charles Gordon Heyd, New York, who spoke on "Cutter, the Medical Educator," and Alphonse M. Schwitalla, S.J., St. Louis, who spoke on "Cutter, the Man." Dr. Wilbur, who presided, read letters of tribute sent from all parts of the country.

APPOINTMENT OF DR. WEISKOTTEN

The Council voted to recommend to the Board of Trustees of the American Medical Association that Dr. Herman G. Weiskotten, a member of the Council on Medical Education and Hospitals and dean of Syracuse University College of Medicine, be appointed Secretary of the Council for at least a period of one year. The Council agreed to propose to the Trustees that Dr. Weiskotten spend three quarters of his time acting as Secretary of the Council and the remainder in the service of his medical school.

The Board of Trustees, meeting on Wednesday, February 18, agreed to this plan.

SPEEDING THE PRODUCTION OF PHYSICIANS TO MEET THE WAR NEEDS

The resolution adopted by the Council on this subject was published in THE JOURNAL, February 28, page 751.

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE

The resolution on this subject was published in THE JOURNAL, February 28, page 751.

UNIVERSITY OF TEXAS MEDICAL BRANCH

It was agreed to accept the invitation to visit the University of Texas Medical Branch as soon as practicable.

ECLECTIC MEDICAL COLLEGE OF CINCINNATI

The Council wishes to report the complete dissolution of the Eclectic Medical College by the Secretary of State of Ohio and the removal of such inhibitions which it has made concerning the recent graduates of this medical college.

REVISION OF ESSENTIALS OF AN APPROVED INTERNSHIP

A resolution was adopted that the revision of the Essentials of an Approved Internship by a subcommittee of the Council be approved and presented to the House of Delegates of the American Medical Association at its next session for ratification.

INSPECTION OF HEALTH RESORTS

At the suggestion of the Board of Trustees of the American Medical Association, Dr. W. W. Bauer, representing the Association's Committee on American Health Resorts, submitted a memorandum requesting the Council on Medical Education and Hospitals to cause its field inspectors to make inspections of health resorts. The Council agreed to sample some of these institutions by visitation and report at the next session of the House of Delegates if such a program can be adopted by the Council. It was the sentiment of the Council that, if it is to take on new duties in this connection, such inspections shall be in consonance with the usual procedure of the Council.

SCARCITY OF INTERNS

With regard to the problem presented by the scarcity of interns and residents, it was suggested that the staff of the Council continue to advise hospitals to conserve the doctor's time for the purely professional clinical work in the hospital and have technical help perform nonprofessional services.

HOSPITAL WORK OF THE COUNCIL

A summary of the work of the Hospital Division of the Council for the year 1941 was presented.

REVISION OF MANUAL OF ESSENTIALS OF GOOD HOSPITAL NURSING SERVICE

The Council participated in a revision of the Manual of the Essentials of Good Hospital Nursing Service, serving with other organizations as a joint committee. The manual under discussion had originally been prepared by the American Hospital Association and the National League of Nursing Education. Other organizations having members on the Joint Committee,

in addition to the Council on Medical Education and Hospitals and the two agencies named, were the American College of Surgeons and the American Nurses' Association. The revision of the manual has been completed.

PREPARATION OF NURSES FOR NATIONAL DEFENSE

The Council was represented at a conference in New York on January 26 and 27, called by the American Council on Education at the request of the National League of Nursing Education and the Association of Collegiate Schools of Nursing. The purpose of the conference was to consider what colleges and universities can do to assist in the preparation of nurses, especially for national defense. Recommendations were formulated regarding preclinical programs, guidance policies and materials, and relative to basic professional programs.

CONTINUATION COURSES

It was announced that the next quarterly publication of opportunities for continuation courses for practicing physicians is scheduled for publication in *THE JOURNAL* sometime in April.

CERTIFYING INTERN SERVICES

A resolution was adopted that the Council continue its present policy of not in any way certifying intern services in institutions which it has no possibility of inspecting.

INSURING CONTINUOUS SUPPLY OF MEDICAL SPECIALISTS

A joint meeting of the Council on Medical Education and Hospitals and the Advisory Board for Medical Specialties was held on February 15. During this meeting the necessity for insuring a continuous supply of adequately trained medical specialists for the Army, Navy, other government services and the civilian needs was clearly recognized, particularly in those fields in which there is a shortage of personnel and a lack of sufficient opportunities for training at the present time. It was felt that a reasonable number of qualified recent graduates should be selected and permitted to continue advanced training under proper auspices. For this purpose a joint committee of the two organizations was appointed consisting of Dr. Robin C. Buerki, Philadelphia; Dr. B. R. Kirklin, Rochester, Minn.; Dr. C. Guy Lane, Boston, representing the Advisory Board for Medical Specialties, and Dr. Reginald Fitz, Boston, Dr. Charles Gordon Heyd, New York, and Dr. H. G. Weiskotten, Chicago, representing the Council on Medical Education and Hospitals.

INVITATION TO INSPECT MEDICAL SCHOOL IN HAITI

Dr. Camille Liérissin, professor in the Faculté de médecine, Port-au-Prince, Haiti, appeared before the Council and invited the American Medical Association to inspect the medical school in Haiti and offered to the medical profession in the United States opportunities for study and research in tropical diseases with suitable accommodations and facilities for work. It was a pleasure to receive Dr. Liérissin, and his visit contributed much to the cultural relationships of the two republics.

CONFERENCE WITH REPRESENTATIVES OF ASSOCIATION OF AMERICAN MEDICAL COLLEGES

A conference was held on February 18 with members of the Executive Council of the Association of American Medical Colleges and the Board of Trustees of the American Medical Association at which problems of mutual interest were discussed. A joint committee was appointed to decide on matters of policy and to make recommendations to the Council and the Association of American Medical Colleges. The committee consists of Dr. A. C. Bachmeyer, Chicago; Dr. Fred C. Zapffe, Chicago, and Dr. E. M. MacEwen, Iowa City, representing the Association of American Medical Colleges, and Dr. Reginald Fitz, Boston; Dr. Charles Gordon Heyd, New York, and Dr. Herman G. Weiskotten, Chicago, representing the Council on Medical Education and Hospitals.

HOSPITALS APPROVED FOR INTERN TRAINING, RESIDENCIES AND FELLOWSHIPS AND TECHNICAL SCHOOLS APPROVED

The Council on Medical Education and Hospitals at this meeting took action as follows regarding hospitals for intern training and for residencies and fellowships, as well as schools for the training of Clinical Laboratory and Physical Therapy Technicians:

Hospitals Approved for Intern Training

St. Joseph's Hospital, San Francisco.
Mercy Hospital, Council Bluffs, Iowa.
Yonkers General Hospital, Yonkers, N. Y.
Cleveland Clinic Foundation Hospital, Cleveland.
Hillcrest Memorial Hospital, Tulsa, Okla.

Approved Residencies and Fellowships

Anesthesiology

University of California Hospitals, San Francisco
Hospital of the University of Pennsylvania, Philadelphia.

Dermatology and Syphilology

Stanford University Hospitals, San Francisco
Charity Hospital, New Orleans
Buffalo General Hospital, Buffalo.

Mixed

Bristol Hospital, Bristol, Conn.
Tewksbury State Hospital and Infirmary, Tewksbury, Mass.
Alexian Brothers Hospital, St. Louis.
Shelburne Arms Hospital, Richmond, Va.

Neurology

George Washington University Hospital, Washington, D. C.

Psychiatry

Mount Zion Hospital, San Francisco
Norwich State Hospital, Norwich, Conn.
Chicago State Hospital, Chicago.
St. Luke's Hospital, Chicago.
Manteno State Hospital, Manteno, Ill.
Peoria State Hospital, Peoria, Ill.
Kalamazoo State Hospital, Kalamazoo, Mich.
Kansas City General Hospital No. 1, Kansas City, Mo.
New Jersey State Hospital, Trenton, N. J.
Pilgrim State Hospital, Brentwood, N. Y.
Harlem Valley State Hospital, Wingdale, N. Y.
Massillon State Hospital, Massillon, Ohio.

Obstetrics

St. Joseph's Hospital, Chicago
City Hospital, Akron, Ohio.

Obstetrics and Gynecology

St. Francis Hospital, Peoria, Ill.

Ophthalmology and Otolaryngology

St. Luke's Hospital, Chicago.

Otolaryngology

University of Kansas Hospitals, Kansas City, Kan.
Jefferson Davis Hospital, Houston, Texas.

Pediatrics

Trinity Hospital, Minot, N. D.

Radiology

Newark Beth Israel Hospital, Newark, N. J.
Good Samaritan Hospital, Portland, Ore.
Jewish Hospital, Philadelphia.

Surgery

St. Francis Hospital, Peoria, Ill.
St. Mary's Hospital, Detroit.
St. Luke's Hospital, Kansas City, Mo.
Peoples Hospital, Akron, Ohio.
Fairview Park Hospital, Cleveland.
Sacred Heart Hospital, Allentown, Pa.
Hermann Hospital, Houston, Texas.
Jefferson Davis Hospital, Houston, Texas.

Schools for Clinical Laboratory Technicians Approved

St. Joseph's Hospital, Phoenix, Ariz.
George Washington University and Hospital, Washington, D. C.
Providence Hospital, Washington, D. C.
St. Bernard's Hospital, Chicago
Norton Memorial Infirmary, Louisville, Ky.
Charity Hospital, New Orleans.
Shreveport Charity Hospital, Shreveport, La.
Burge Hospital, Springfield, Mo.
St. Joseph's Hospital, Elmira, N. Y.
St. Joseph's Hospital, Reading, Pa.
St. Joseph's Hospital, Memphis, Tenn.
Jefferson Davis Hospital, Houston, Texas.

School for Physical Therapy Technicians Approved

University of Minnesota, Minneapolis.

H. G. WEISKOTTEN, M.D., Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ILLINOIS

Dental Correction Program Inaugurated.—The state department of health has announced a program in defense areas to correct dental defects on young children whose parents cannot afford to pay for the work. The program has the cooperation of the Illinois State Dental Society and the U. S. Children's Bureau. Educational programs will be carried out and as far as resources will permit, costs of dental care for "dentally indigent children" will be made from state funds, local funds or both.

Chicago

All Expense Tour to Federation Meeting.—Dr. Arno B. Luckhardt of the University of Chicago announces an all expense tour for Chicago physicians to the annual meeting of the Federation of American Societies for Experimental Biology in Boston, March 31-April 4. Additional information may be obtained from Dr. Luckhardt by calling the University of Chicago, Midway 0800, local 320. An announcement concerning the meeting appears in this issue of *THE JOURNAL* under General News, page 1153.

Capps Prize Awarded.—Dr. Arnold Lazarow has been given the Joseph A. Capps Prize in Medical Research for 1941 for his study on "Particulate Glycogen: A Submicroscopic Component of the Guinea Pig Liver Cell; Its Significance in Glycogen Storage and the Regulation of Blood Sugar," according to an announcement from the Institute of Medicine. Dr. Lazarow graduated at the University of Chicago School of Medicine in 1941. The Capps Prize is given to a young physician for the most meritorious investigation in medicine or in the specialties of medicine.

INDIANA

Tristate Meeting.—The Northern Tri-State Medical Association will hold its sixty-ninth annual meeting at Fort Wayne on April 7 with sessions in the Chamber of Commerce Building. The Allen County Medical Society will act as host, and headquarters will be the Hotel Keenan. The following will participate:

- Dr. Claire L. Straith, Detroit, Treatment of Facial Injuries and Deformities.
- Dr. Irvine H. Page, Indianapolis, Nature and Experimental Treatment of Hypertension.
- Dr. Paul Starr, Chicago, Clinical Studies of the Pituitary Factor in Patients with Thyroid Disease.
- Dr. Nicholson J. Eastman, Baltimore, Breech Presentation and Problems Associated Therewith.
- Dr. Paul B. Magnuson, Chicago, Surgical Treatment of Arthritis.
- Dr. Frederick F. Yonkman, Detroit, Sulfur Derivatives.
- Dr. Jonathan Forman, Columbus, Ohio, Importance of Allergy in General Practice.
- Dr. Beveridge H. Moore, Chicago, the A B C of Orthopedics.
- Dr. Arthur H. Parmelee, Chicago, Bone Growth in Early Infancy.
- Dr. William S. Keller, Glendale, Ohio, Civilian Defense and the Doctor.

IOWA

Graduate Lectures.—The Polk County Medical Society, Des Moines, sponsored two graduate lectures, March 13, at the Yonkers Tea Room, Des Moines. Dr. Elexious T. Bell, Minneapolis, discussed "Kidney Disease" and Dr. Charles Anderson Aldrich, Winnetka, Ill., "Treatment of Chronic Nephritis and Nephrosis."

Annual Pediatric Session.—The Iowa State Pediatric Society will hold its annual meeting at the Hotel Fort Des Moines on April 14. The following program will be presented:

- Dr. Mark L. Floyd, Iowa City, Neuritis.
- Dr. Robert O. Hughes, Ottumwa, Medical Treatment of Pyloric Spasm and Pyloric Stenosis.
- Dr. Charlotte Fisk, Des Moines, Fluid Therapy in Pediatrics.
- Dr. Robert H. McBride, Sioux City, Scurvy.
- Dr. Martin D. Ott, Davenport, Pediatrics, Past and Present.
- Dr. Philip C. Jeans, Iowa City, Metabolic Changes in Adolescence.
- Dr. James E. Dyson, Des Moines, Kenny Treatment of Acute Poliomyelitis.
- Dr. Dennis H. Kelly, Des Moines, Extensions from the Primary Complex in Tuberculosis.
- Dr. John A. Toomey, Cleveland, Newer Prophylactic Measures.

In the evening Dr. Toomey will address the banquet session on "Pathogenesis and Treatment of Poliomyelitis."

MARYLAND

Professor Hegner Dies.—Robert W. Hegner, Ph.D., since 1922 professor of protozoology of the Johns Hopkins University School of Hygiene and Public Health, Baltimore, died, March 11, aged 62. Dr. Hegner was born in Decorah, Iowa, in 1880. He received his Ph.D. degree at the University of Wisconsin, Madison, in 1908. For a time he served as an assistant zoologist at the University of Chicago, professor of biology at the Wisconsin State Normal School, River Falls, Wis., and assistant zoologist at the University of Wisconsin. He was on the staff of the University of Michigan, Ann Arbor, Mich., from 1908 to 1918, when he joined Johns Hopkins as an associate. He was associate professor in charge of the department of medical zoology there from 1920 to 1922, when he became professor of protozoology. In 1926 Dr. Hegner once served as exchange professor with the London School of Hygiene and Tropical Medicine and in 1929 visiting professor at the school of hygiene and public health, University of Philippines. He was a member of many scientific societies, including the American Society of Tropical Medicine and the Academy of Tropical Medicine, serving as president of the American Society of Parasitology in 1936.

MASSACHUSETTS

The Howe Lecture of Ophthalmology.—Marion Hines, Ph.D., associate professor of anatomy, Johns Hopkins University School of Medicine, Baltimore, gave the Howe Lecture of Ophthalmology at Harvard Medical School, Boston, on March 17. His subject was "Recent Contribution to the Localization of Vision Within the Central Nervous System." The lecture is given under the auspices of the Howe Laboratory of Ophthalmology at Harvard.

Forty Years' Service with Health Board.—Dr. Frank L. Morse, Somerville, has retired after forty years' service with the Somerville Board of Health. According to the *New England Journal of Medicine* Dr. Morse was medical and sanitary inspector of the Massachusetts Board of Health from 1898 to 1905 and a district health officer from 1909 to 1915. From 1901 until his retirement from the Somerville board he had been in charge of the bacteriologic laboratory, the contagious disease hospital, contagious disease control and all other medical work of the board. He was discharged from active service in the U. S. Army in 1919 with the rank of lieutenant colonel and was retired from the Officers Reserve Corps in 1935 with the rank of colonel. He graduated at Harvard Medical School in 1894.

MICHIGAN

Society News.—Dr. Austin E. Smith, Acting Director, Council on Pharmacy and Chemistry, American Medical Association, Chicago, addressed the medical section meeting of the Wayne County Medical Society with the Detroit Retail Druggists Association in Detroit, March 9, on "The Role of the Physician, Pharmacist and Government in the Control of Drugs."

MINNESOTA

Abortionist Sentenced.—Millie Meyer, Duluth, was sentenced on February 11 to a term of not to exceed four years at hard labor in the Women's Reformatory at Shakopee, following a conviction by a jury of the crime of abortion. Mrs. Meyer was arrested on January 15, the preliminary hearing was held on January 22, and the trial started on February 3.

Course in Roentgenology of the Head and Neck.—The Center for Continuation Study of the University of Minnesota, Minneapolis, will conduct a course on roentgenology of the head and neck, March 30-April 1. Members of the medical school faculty are assisting in the course. Registrants are invited to attend the meeting of the Minnesota Radiological Society at the Mayo Clinic, Rochester, March 28, for a dinner and evening program. A special course in roentgenology of the teeth will be given on April 2 if a sufficient number of roentgenologists register.

NEBRASKA

New Health Units.—The Nebraska State Department of Health has established three new health units in defense areas: Cass-Sarpy County, Douglas County, including the city of Omaha, and Dodge-Saunders County. These units are established in connection with either army or defense production, and the personnel consists of medical officer, engineer, sanitarian and six nurses.

Society News.—The Omaha-Douglas County Medical Society will be addressed, April 14, among others, by Dr. James Dewey Bisgard, Omaha, on "Sarcoma of the Duodenum." The society devoted its February 24 meeting to a symposium on heart disease at which the speakers were Drs. Frederick W. Niehaus, Raymond L. Traynor, Augustus David Cloyd, Howard B. Hunt and Michael William Barry.

NEW YORK

Lecturer on Rheumatic Fever.—The Medical Society of the State of New York and the state department of health have arranged a special lecture on rheumatic fever for the Steuben County Medical Society to be given at Corning, April 9. Dr. Norman S. Moore, Ithaca, will be the speaker.

Milk Borne Outbreak of Septic Sore Throat.—*Health News* reports an outbreak of septic sore throat in Suffolk County, traced to a milk handler who was suffering from sore throat. All the persons affected in the outbreak were patrons of one milk producer and dealer who sold the greater part of his supply as raw milk. Only those who drank the raw milk became ill. The milk handler was sick nine days before the beginning of the outbreak. He carried on his duties, cleaning the cattle for milking, transporting cans of milk, washing bottles and assisting in bottling the milk. One of the cows sustained an udder injury, and this milk handler took care of the cow's injury. Strains of hemolytic streptococci belonging to Lance-have arranged a special lecture on rheumatic fever for the Steuben County Medical Society to be given at Corning, April 9. Dr. Norman S. Moore, Ithaca, will be the speaker.

New York City

Graduate Course.—Columbia University announces a short course in practical oral pathology, April 1-29. The course will consist of lectures, discussions and demonstrations and is open to qualified graduates in dentistry or medicine.

Ship's Doctor Missing.—Dr. Ralph M. Whithead, for more than thirty-five years ship's doctor on various boats, has been reported missing following the torpedoing of a ship in the Caribbean, March 6, according to the *Chicago Tribune*. Dr. Whithead graduated at the University of Illinois College of Medicine, Chicago, in 1890. He is 75 years of age.

Dr. Rappleye Resigns as Commissioner of Hospitals.—Dr. Willard C. Rappleye, since Oct. 1, 1940 commissioner of hospitals, has resigned to return to his activities as dean of Columbia University College of Physicians and Surgeons. At the time of his appointment, Dr. Rappleye was granted a fifteen months leave of absence from his deanship. He succeeded Dr. Sigismund S. Goldwater, who resigned to devote his full time as head of Associated Hospital Service.

Psychology Laboratory Observes Fiftieth Anniversary.—The fiftieth anniversary of the founding of the laboratory of psychology of Columbia University was celebrated at a dinner meeting on February 12. Dr. McKen Cattell, since 1936 associate professor of pharmacology in charge of the department, Cornell University Medical College, was the guest. Dr. Cattell established the laboratory in 1891. Albert T. Poffenberger Jr., Ph.D., executive officer of the department of psychology at Columbia, presided at the dinner, and addresses were made by Nicholas Murray Butler, LL.D., president of the university; Edward L. Thorndike, LL.D., director, division of psychology, Institute of Educational Research, Teachers College at Columbia; Robert S. Woodworth, Ph.D., professor of psychology at the school, and Dr. Cattell.

Visiting Professorships Established.—The Long Island College of Medicine, Brooklyn, has established a series of visiting professorships under a grant from the Commonwealth Fund of \$4,500 a year for three years. On the concept that all departmental heads have phases of their teaching program they would like to strengthen, the college is inviting scholars from other institutions for short periods to make specific contributions to the curriculum, according to an announcement. Dr. Thomas Addis, professor of medicine, Stanford University School of Medicine, San Francisco, is the first visitor under the new plan and started his six weeks affiliation with the school on March 16 as the guest of Dr. Tasker Howard, professor of medicine. Dr. Wilson G. Smilie and members of his staff at Cornell University Medical College have accepted the invitation of Dr. Wade W. Oliver, professor of bacteriology, to give the spring trimester course in parasitology and tropical medicine to the second and third year classes.

Hospital Unit Dedicated.—Ceremonies on January 4 marked the dedication of a new nine story building constructed as the major part of a \$1,300,000 modernization program at St. Vincent's Hospital, New York. The new unit adds one hundred and twenty-four beds to the existing four hundred and seventy beds of the hospital. The fourth, fifth and sixth stories are set aside for the maternity department. The ninth story is divided into two parts, the front containing two operating rooms with adjoining sterilizing, doctors' wash-up and anestheticizing rooms. The rear portion of the ninth story contains a complete delivery department, having three delivery rooms together with labor rooms and the necessary utilities. Above the ninth story is provided a roof pavilion for outdoor treatment together with a large solarium. St. Vincent's Hospital was established ninety-two years ago, expanding from thirty beds in 1849 to its present approximate capacity of six hundred beds. At a dinner on January 12 a campaign was launched to raise \$750,000 to cover part of the cost of the modernization program at the hospital.

OKLAHOMA

Personal.—Dr. Lewis L. Recse has resigned as medical director of the State University and Crippled Children's hospitals, Oklahoma City, and has been succeeded by Dr. George N. Barry, Oklahoma City, as acting medical director.—The University of Oklahoma School of Medicine closed for a time on December 4 as a tribute to Dr. Richard C. Lowry, professor of clinical obstetrics, who died suddenly, December 2.

PENNSYLVANIA

Dr. Daugherty Wins Seibert Award.—The Harrisburg Academy of Medicine recently presented the Seibert Memorial Award for 1941 to Dr. John Arthur Daugherty, Harrisburg, now president of the Dauphin County Medical Society. The award is granted every two years to the member of the Harrisburg Academy of Medicine, under 45 years of age, who, in the opinion of the committee, has done most to advance the practice of medicine in the community. Dr. Daugherty was for five years secretary of the Dauphin County Medical Society and business manager of the *Academician*. In 1936 he was largely instrumental in organizing the Physicians' and Dentists' Bureau for the benefit of the professions, which led to the forming of the Capital Hospital Service, of which he later served as secretary. The award of \$500 for graduate study was established as a memorial to the late Dr. William Henry Seibert, Steelton.

Philadelphia

Scarlet Fever Outbreak.—Forty-three new cases of scarlet fever were reported in Philadelphia on March 6, bringing the total this year to 1,358. The city council's finance committee voted \$14,400 to be used in preventing a spread of the epidemic. Of the 636 patients in the city's contagious disease hospital, 554 were scarlet fever patients at the time of this report.

Meeting on Nutrition.—The Philadelphia County Medical Society devoted its meeting, March 11, to a round table on nutrition with Dr. David T. Smith, professor of bacteriology and associate professor of medicine, Duke University School of Medicine, Durham, N. C., as guest speaker discussing "Recent Advances in the Vitamin Field of Practical Importance in Therapy." Members of the panel were Drs. Katharine O'Shea Elsom, Herbert T. Kelly, Waldo E. Nelson, George Harlan Wells, John H. Willard and Michael G. Wohl.

Meeting on Nutrition and Defense.—The Woman's Auxiliary to the Philadelphia County Medical Society announces the twelfth annual health institute in the society's auditorium, April 14, with Mrs. Francis F. Borzell presiding. "Nutrition and Defense" will be the theme. The speakers will be:

Dr. Katharine O. Elsom, Vitamins in Relation to National Defense.
Dr. John H. Gunter, Nutrition and the Teeth.
Dr. Earl D. Bond, Nutrition and the Emotions.
Mrs. Charles C. Crouse, Greensburg, Pa., The Responsibility of the Doctor's Wife in This Crisis.
Dr. Gilson Colby Engel, Cancer As It Concerns You.
Dr. Arthur Parker Richards, First Lieut. Colonel, U. S. Army, Nutrition, Health and the Soldier's Job.
Dr. Lewis C. Brown, Pa., Organized Efforts in Medical Defense.

RHODE ISLAND

Personal.—Dr. Peter Pineo Chase, Providence, has been appointed editor of the *Rhode Island Medical Journal*, succeeding Dr. Albert H. Miller, Providence, who has retired after more than five years in the position.—The Men's Club of Temple Emanu-El recently presented Dr. Herman C. Pitts with its yearly award "to a citizen of Providence for outstanding achievement in the field of civic improvement, human betterment and advancement of American ideals."

Society News.—The Providence Medical Association devoted its meeting, March 2, to a symposium on hypertension with the following speakers: Drs. Morgan Cutts, Robert R. Baldrige and Clifton B. Leech. All are of Providence. The association was addressed on February 2 in joint session with the Rhode Island Medical Society by Drs. Allen O. Whipple and Louis Bauman, New York, who discussed therapy of pancreatic disease and Dr. Walter G. Phippen, Salem, Mass., "The Procurement and Assignment Service for Physicians."

New Pathologic Society.—Announcement is made of the organization of the Rhode Island Society of Pathologists at a meeting in Howard. Officers include Drs. Benjamin Earl Clarke, Providence, president, and Louis Goodman, Howard, secretary-treasurer. Active membership is open to graduates of recognized medical schools who have specialized in the practice of pathology or who occupy positions as pathologists in approved hospitals. The group aims to provide periodic conferences for mutual assistance, to maintain and improve the services of the pathologist to the physician and patient, and to stimulate productive work in the field of pathology.

VIRGINIA

Young Physician Prisoner of War in Japan.—Lieut. Richard Bland Williams Jr., Portsmouth, on duty at the Naval Hospital in Guam when the island was taken by the Japanese, is a prisoner in Japan, according to a message published in the *Norfolk Pilot*, February 18. Dr. Williams graduated at the University of Virginia Department of Medicine, Charlottesville, in 1939 and later served at the Norfolk Naval Hospital in Portsmouth. He is 27 years of age.

Change in Graduate Instruction.—At a specially called meeting to decide on the year's program, the department of clinical and medical education of the Medical Society of Virginia agreed that a change of emphasis in postgraduate instruction was necessary. The usual clinics at the medical schools, which have been a part of the program in the past, will not be included because of war conditions and the increased demands on practicing physicians and the medical school staffs. The department will, however, continue to furnish speakers and assist financially in sponsoring local programs, especially in the field of industrial medicine and military medicine.

An Experiment in Nutrition.—Two sections of Richmond have been selected as test areas for an intensive campaign intended ultimately to improve the nutritional standards of the American people. According to the state medical journal, Virginia was selected for this experiment because of the state's historical background, its highly cooperative volunteer service for defense and the ready availability of personnel for the experiment. Cooperating with the city and state health departments are the Medical College of Virginia, Richmond, Virginia Defense Council, Federation of Woman's Clubs, Richmond Home Economics Association, Richmond Academy of Medicine, Federation of Parent Teachers Associations, Richmond Dental Society, the junior league, the citizens' league defense program of the Office of Civilian Defense, the Dairy Council, Virginia Tuberculosis Association, Colored Recreation Association, WPA division of community service programs, Richmond Public Library, Richmond Social Service Bureau, Richmond Dietetic Association and the Farm Security Administration. Organization and instruction programs will be carried out, and surveys will be made to determine changes in consumers' buying habits. One study already completed has shown that only about 10 per cent of the children in an elementary school in Richmond are selecting or bringing from homes balanced lunches. The program is under the direction of the Office of Defense Health and Welfare Services.

WISCONSIN

Annual Spring Clinics.—The Wisconsin State Medical Society will hold its annual spring clinics in Chippewa Falls on April 27, in Wausau on April 28 and in Fond du Lac on April 29. Participating will be:

Walter Zeit, Ph.D., Milwaukee, Anatomy of the Female Pelvis and Anatomy of Stomach and Gallbladder.
Dr. Howard H. Cummings, Ann Arbor, Mich., Postpartum Care: Repair of Lacerations and Episiotomy Wounds; Complications of Menopause.
Dr. Walter L. Palmer, Chicago, Functional Colitis; Peptic Ulcer, Surgical Management.
Dr. William C. Keettel Jr., Madison, Obstetrical Manikin Demonstration.
Dr. William S. Middleton, Madison, Carcinoma of the Lung.
Dr. Stephen E. Gavin, Fond du Lac, The Medical Profession and the War.
A series of round table dinners will conclude each program.

GENERAL

Citations for Distinguished Service.—During the annual dinner of the Birth Control Federation of America, Inc., New York, January 28, citations for distinguished service in the advancement of human welfare were awarded to Pearl S. Buck, New York, author; Paul U. Kellogg, New York, editor, *Survey Graphic*; Julian S. Huxley, author; Dr. Carl V. Reynolds, Raleigh, state health officer of North Carolina, and Dr. George M. Cooper, Raleigh, assistant state health officer of North Carolina.

Special Society Election.—Selman A. Waksman, Ph.D., New Brunswick, N. J., was elected president of the Society of American Bacteriologists at its annual meeting in Baltimore recently. Rebecca Lancefield, Ph.D., of the Rockefeller Institute for Medical Research, New York, was named vice president, and William B. Sarles, Ph.D., Madison, Wis., secretary-treasurer. Ira L. Baldwin, Ph.D., Madison, who had been secretary for a number of years, was reelected secretary but was compelled to resign on account of ill health. The society adopted a resolution honoring Dr. Baldwin for his service.

Industrial Physicians and Surgeons.—The twenty-seventh annual meeting of the American Association of Industrial Physicians and Surgeons and the third annual meeting of the American Industrial Hygiene Association will be held at the Hotel Gibson, April 13-17. Included among the speakers will be:

Dr. Harold C. Habern, Rochester, Minn., The Health of the Executive
Dr. James Barrett Brown, St. Louis, Advances in Skin Grafting
Eugene W. Scott, Ph.D., Cincinnati, Metabolism of Nitroparaffins
Dr. Willard F. Macble and Edward J. Largen, A.B., Cincinnati, Absorption, Retention and Excretion of Fluorides at Normal and Abnormal Levels of Intake.
Dr. Francis F. Heyroth and Jacob Cholak, Ch E, Cincinnati, Toxicity of Aluminum.
Frederick H. Goldman, Ph.D., Washington, D. C., Analysis of Atmospheric Samples of Explosive Chemicals
L. P. Pekrul, Robert C. Lewis, Ph.D., and Donald E. Cummings, B.S., Denver, A Reliable Procedure for the Evaluation of Exposure to Lead by Spot Urine Sampling.

One session on Wednesday will be devoted to a symposium on lead poisoning. Another symposium will cover "Medical Service for the Small Plant." The Knudsen Award will be presented at the annual dinner, Wednesday evening.

Regional Meeting on Physical Therapy.—The Eastern Section of the American Congress of Physical Therapy will hold its spring session in Philadelphia, April 11, in conjunction with the Connecticut Physical Therapy Society, the New Jersey Society of Physical Therapy Physicians, the New York Physical Therapy Society and the Pennsylvania Academy of Physical Medicine. Included among the speakers will be:

Dr. Harold Lefkoe, Philadelphia, The Office Use of the Paraffin Bath
Dr. Richard Kovacs, New York, Painful Shoulders
Dr. Stella S. Bradford, Montclair, N. J., Posture and Its Relation to Health and Disease.
Dr. Charles R. Brooke, New York, Physical Measures in the Treatment of Veterans.
Dr. William H. Schmidt, Philadelphia, Presentation of Clinical Cases from the Department of Physical Therapy of the Jefferson Hospital
Dr. Alexander Hersh, New York, The Influence of Hot and Cold Applications on Temperature in the Mouth.
Dr. Winthrop M. Phelps, Baltimore, Recent Trends in the Treatment of Cerebral Palsy.
Drs. Frederick M. Allen and Lyman W. Crossman, New York, Refrigeration Anesthesia for Extremity Surgery
Dr. Washington Merscher, New York, Mobilizing American Spas

Research on Problems of Alcohol.—According to *Science* the Research Council on Problems of Alcohol has the following studies under way:

A critical survey of all work completed to date on the effects of alcohol on the individual by the New York University College of Medicine, with a grant of \$25,000 from the Carnegie Corporation.

A study of toxic factors in alcoholism by the New York State Psychiatric Institute, with a grant of \$1,500 from the American Philosophical Society. The minimum value of services and facilities contributed by the institute is \$2,200.

A study of the role of alcohol in liver cirrhosis by the New York University College of Medicine, with two grants, \$2,100 and \$1,500, from the Dazian Foundation for Medical Research. The minimum value of services and facilities contributed by the university is \$7,200.

A study of reactions resulting from the ingestion of alcohol, for the ultimate purpose of discovering how a craving for alcohol is established, by the Phipps Psychiatric Clinic of Johns Hopkins University, with a grant of \$1,800 from the council's research fund. The minimum value of services and facilities provided by the clinic is \$3,750.

What happens to patients discharged as "cured" from the institutions for alcoholics by Columbia University, with a grant of \$7,500 (for the first year) from the council's research fund.

The effects of maternal alcohol ingestion on the fetal cortex by the Medical College of Virginia, Richmond, with a grant of \$1,315 from the council's research fund. The minimum value of services and facilities provided by the Medical School is \$500.

An informal survey of a town of four thousand people to reveal the extent of alcoholism and the adequacy of measures now in use for its treatment by E. M. Jellinek of the Laboratory of Applied Physiology of Yale University. This study is being carried on to provide for the experimental use of techniques being considered for a more extensive study.

Report on Youth Health Program.—More than a quarter of a million young persons have been given complete physical examinations since the national youth health program was instituted in September 1940, according to a recent report. Preliminary studies on the sixty-one thousand examinations showed that, while 70 per cent of the youths were found to be physically fit for any type of employment, medical and dental care was recommended for four out of five of the young people examined. The health program serves to reduce the number of young workers rejected by industry because of physical defects and at the same time opens the way for rehabilitation of many who would otherwise be unable to contribute to the war effort. On July 1, 1941 the National Youth Administration established the Youth Work Defense Program, which it operates under the supervision of Lieut. Col. Nathaniel A. Burnell, director of defense training for both the Federal Security Agency and the Office of Production Management. This program consists of seven hundred and sixty-one local production projects and one hundred and seventy-five resident center projects, which comprise almost one thousand nine hundred shop units. These projects are distributed throughout the country, in all states and in most counties. During the period July 1941 through December 1941 more than one hundred and ninety thousand youths who received their work experience on NYA projects were able to obtain jobs in industry. More than thirteen thousand young workers were gaining experience in hospital duties through service as nurses' aides or ward attendants.

Federation of Societies for Experimental Biology.—The twenty-ninth annual meeting of the Federation of American Societies for Experimental Biology will be held in Boston, March 31-April 4. Each of the constituent societies will have its own headquarters as follows: Physiology, Hotel Statler; Biochemistry, the Copley-Plaza; Pharmacology, the Brunswick; Pathology, the Parker House, and Nutrition, Hotel Lenox. At a joint session of all groups in the Hotel Statler the following program will be offered:

Edward A. Doisy, Ph.D., St. Louis, Metabolism of Estrogens.
John R. Murlin, Ph.D., Rochester, N. Y., Nutritional Problems in Relation to the Nation's Health.
Dr. Ralph M. Waters, Madison, Wis., Newer Viewpoints on Clinical Anesthesia.
Frieda S. Robscheit-Robbins, Ph.D., Rochester, N. Y., Amino Acids in Hemoglobin Formation.
George O. Burr, Ph.D., Minneapolis, Significance of the Essential Fatty Acids.

There will be symposiums on vitamins and enzyme action, the metabolism of protein, contributions of physics to biochemistry and on morphine problems, deficiency diseases and mechanism of secretion. The Mead Johnson & Company "B Complex" Award will be presented during the first day's session of the American Institute of Nutrition on Wednesday. Thursday morning the pathologists will meet with the American Association of Immunologists. On Friday there will be a round table conference of the Biochemistry group with the Biometric Section of the American Statistical Association. The constituent societies of the federation are the American Physiological Society, the American Society of Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics, the American Society for Experimental Pathology and the American Institute of Nutrition.

National Tuberculosis Meeting.—The thirty-eighth annual meeting of the National Tuberculosis Association will be held at the Bellevue-Stratford Hotel, Philadelphia, May 6-9. The thirty-seventh annual meeting of the American Trudeau Society and the eighteenth annual meeting of the National Conference of Tuberculosis Secretaries will be held simultaneously. According to the preliminary program there will be panel discussions on "The Management of Patients with Occasional Positive Sputum After Apparently Adequate Therapy" and on the "Treatment of Postoperative Complications." Among the speakers on the program will be:

Dr. Walter K. Whitehead, Northville, Mich., The Physiological Function of the Two Lungs Separately Under Varying Conditions.
S. Reid Warren Jr., Sc.D., Philadelphia, Technical and Economical Factors Associated with the Production of Miniature Chest Roentgenograms.
Dr. Robert G. Bloch, Chicago, The Roentgenographic-Pathologic Correlation of Tuberculous Calcifications in the Lung.
Dr. Chevalier L. Jackson, Philadelphia, The Development of Bronchoscopy.
Florence B. Seibert, Ph.D., Philadelphia, Immunological Processes in Tuberculosis as Determined by Electrophoresis of the Blood.
William H. Feldman, M.S., and Drs. Horton Corwin Hinshaw, Frank C. Mann of Rochester, Minn., The Effect of Promin on Experimental Tuberculosis in the Guinea Pig.

On Thursday there will be one session devoted to "The Historical and Social Significance of the Tuberculosis Movement" and on Friday a symposium on "Tuberculosis Associations and National Defense." Dr. Henry C. Sweeney, Chicago,

will be chairman at a diagnostic and therapeutic clinical conference, Friday evening. The session will conclude Saturday morning with the following program:

Dr. Louis E. Siltzbach, New York, Medical Aspects of the Rehabilitation of the Tuberculous.
Dr. George H. Gehrmann, Wilmington, Del., Industry's Responsibility for the Worker's Health.
Dr. Arthur N. Aitken, Lockport, N. Y., Clinical Criteria for Determining Tolerance Following Pulmonary Tuberculosis.
Dr. J. B. McDougall, London, England, Tuberculosis and the War in England, paper to be read by Dr. George J. Wherrett, Ottawa, Ontario, Canada.

The fifteenth anniversary dinner of the Pennsylvania Tuberculosis Society will be held Thursday night.

LATIN AMERICA

Hospital News.—Ceremonies were recently held to lay the cornerstone of a new municipal medicosurgical teaching hospital at Avenida 28 de Setembro of Rio de Janeiro.

New Director of Public Health in Haiti.—Jules Thebaud, D.D.S., Port au Prince, Haiti, was appointed director of the National Department of Hygiene and Public Health in Haiti, January 16. Dr. Thebaud graduated at the University of Montreal in 1923. He has been director of the dental school in Port au Prince since 1928. He is the founder and president of the Société Dentaire d'Haiti. Dr. Thebaud has taken graduate work at the New York College of Dentistry, Forsythe Dental Infirmary of Boston, University of Havana, Northwestern University and Columbia University, New York.

Government Services

National Conference on Industrial Hygiene

The fifth annual meeting of the National Conference of Governmental Industrial Hygienists will be held in Washington, D. C., April 9-11. Among the many papers to be presented at this meeting are the following: Mr. Verne A. Zimmer, director, Division of Labor Standards, U. S. Department of Labor, Washington, D. C., "The Activities of the Committee for the Conservation of Manpower in War Industries" and Dr. John G. Cunningham, Toronto, Canada, Province of Ontario Department of Health, "Canadian Experience in War Industries."

Dr. Heacock to Coordinate Work of State Divisions

Lyman D. Heacock, D.D.S., Bethesda, Md., formerly of the California State Department of Health, has been appointed to the Division of Industrial Hygiene of the National Institute of Health to coordinate the work of the state divisions of dental health and industrial hygiene with the various plants and nonofficial agencies concerned with maintaining dental health. Dr. Heacock was to begin his work in Alabama on March 3. He will be available to any state requesting his services through the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md.

Dr. Fulton Named Health Chief in Bureau of Mines

Dr. William B. Fulton, Harrisburg, Pa., senior surgeon, U. S. Public Health Service Reserve, has been appointed chief of the health division in the Bureau of Mines, U. S. Department of the Interior. He will direct the bureau's expanding activities in safeguarding the physical welfare of thousands of workers in the mineral industries. The health division and safety branch seeks to reduce the occurrence of occupational diseases in these industries by the investigation of gases, dusts and other atmospheric contaminants, and by the development of adequate safeguards against such hazards. Physiologic studies of occupational diseases and the examination of respiratory devices such as gas masks are also a part of the work. Dr. Fulton graduated at the University of Pittsburgh School of Medicine in 1929. After completing his residency he practiced medicine for four years. In 1934 he became chief of the division of industrial hygiene of the Pennsylvania Department of Labor and Industry. Two years later he was transferred to the Pennsylvania Department of Health and appointed director of the Bureau of Industrial Hygiene, where he remained for five years. In January of this year he was appointed senior surgeon in the public health service reserve and detailed to duty with the Bureau of Mines. In 1941 Dr. Fulton received his master's degree in public health at the University of Pennsylvania.

Feb. 7, 1942.

The Otolaryngologist in the War

At the Section of Laryngology of the Royal Society of Medicine the problems of the otolaryngologist in the war were discussed. The president, Mr. E. D. D. Davis, said that at the outbreak of war the work of the specialist, hospital and private, almost disappeared. He hoped that in the Emergency Medical Service (for the civilian war casualties) otolaryngologists would insist on sufficient staff, equipment and accommodation for efficient service and that in the army otolaryngology would no longer be the Cinderella of the specialties. Relatively few otolaryngologists could be adequately employed in their own specialty in the army, and the question was how to occupy them fully. The successful practice of otolaryngology required a sound knowledge of surgery; the otolaryngologist must not confine his attention to the ear, nose and throat. He could be trained in a short time as a war surgeon. The president suggested that ear, nose and throat work should be concentrated in one well equipped unit in each sector of the emergency hospital service, naval base, army command and air force hospital, each unit to have a minimum of two surgeons and assistants.

Surgeon Rear-Admiral C. P. G. Wakeley said that in the navy the ear, nose and throat surgeon also served as a general surgeon. In many instances there would not be enough work for him to do if he was limited to his specialty. As a rule, junior medical officers were selected for the work. They were given practical courses and then sent to the large base hospitals to take over a department under a senior who was a surgical specialist. After experience at the base hospital for two or three years, the young surgeon went to sea and probably became a specialist of his squadron. But during all this time he was doing general surgery.

Major D. Guthrie said that the military practice of the specialty differed considerably from the civil. Radical operations requiring long after-treatment had little place in the army. The object was to return the man to his unit as fit and as quickly as possible. The cases came under three heads: (1) routine cases, such as tonsillitis, deviated septum and various forms of sinusitis, (2) chronic otitis, still very common in the army and largely the result of long neglect, and (3) headache persisting after correction of errors of refraction and calling for attention to the ear, nose or throat.

A Survey of the London Hospitals

The hospital system of this country, like many other things, will probably undergo changes as a result of the war. In the House of Commons the minister of health stated that in connection with the government's postwar policy he had ordered a survey of the hospitals (other than mental hospitals) of London and the surrounding area. The object is to ascertain what area would appropriately be served by a hospital system centered on London and what modifications or extensions of the existing hospital facilities would be desirable. The surveying officers will be Dr. A. H. M. Gray (dermatologist and president of the Royal Society of Medicine) and Dr. Andrew Topping (deputy health officer and school medical officer for the county of London). The former is associated with the voluntary hospitals, the latter with the municipal hospitals. But they have not been chosen as representatives of these two aspects of the problem. Their qualification is a large experience in separate fields of hospital administration. They are to advise how hospitals can give the best service to the public. The question of teaching will be separately considered.

American Red Cross Aid to Britain

American Red Cross supplies to Britain are to be continued in spite of America's entry into the war. In a cablegram just received from the American Red Cross headquarters in Washington the chairman, Mr. Norman Davies, states that "While developments may curtail or restrict the movement of relief supplies to Great Britain, primarily because of increased difficulties of procurement and shipping, the American Red Cross does not contemplate drastic reduction of relief to Britain because of our entry into the war. While immediate and emergency needs in the Pacific may require some dispersion of supplies intended for Great Britain, our resources should be adequate to meet all urgent British needs which cannot be otherwise provided by lend-lease and which are within the scope of the established program of the American Red Cross. Its aid to Britain has now reached a total of \$37,800,000. A further \$3,100,000 worth of relief supplies has been sent to the Middle East.

Rehabilitation of the Injured

In an address on the emergency hospital service Mr. Ernest Brown, minister of health, said that at the beginning of the war the hospitals were expected to receive thousands, even hundreds of thousands, of civilian casualties from air raids. There was a lull until the last four months of 1940, during which 80,000 casualties were treated in hospitals or first aid posts. The emergency hospital service was now no longer only a casualty scheme but one that tried to meet all new war needs as they arose. Specialist treatments were developed in selected centers. They included (1) orthopedic centers, which numbered twenty-one and covered all aspects of fracture treatment from the initial setting to physical therapy, remedial exercises and occupational therapy, (2) fracture departments (a), which numbered fifty-six and differed from the preceding only in not containing the highly specialized equipment for certain more difficult cases, (3) fracture departments (b), which numbered two hundred and thirteen and were mainly hospitals that in peacetime might be suitable for the second category but were now unsuitable for long stay cases owing to their vulnerable situation, and (4) fracture departments (c), which filled the gaps in areas which the hospitals did not conveniently cover.

THE RESTORATION OF WORKING CAPACITY

This organization, with its four hundred and twenty-six establishments and eminent surgeons to advise the staff in every region aimed at the fullest possible restoration of working capacity and the training of and resettlement of the disabled person in a suitable occupation. Arrangements have been made for contact between the patient, his surgeon and a Ministry of Labor officer. This officer interviews the patient before he leaves the hospital and gives advice when the patient has decided what trade he is going into. A training course is arranged. Thus the emergency hospital service has made a great advance on the prewar treatment, which varied according to the initiative and resources of the local hospital. The entire treatment and retraining are correlated. The minister of health claimed that the rehabilitation organization has come to stay.

The Bread Controversy

There seems to be no end to the bread controversy. Acting on the advice of the Medical Research Council, the government ordered the production of "national wheatmeal flour" of 85 per cent extraction instead of the usual 73 per cent. The council recommended that flour for the bread of the people should contain the germ of the wheat grain, as much as possible of the aleuron layer and the finer portion of the bran. The object was that the flour should contain as much as possible of the B vitamins and protein. The importance of a bread made with such protective qualities during this period of dietetic restriction is recognized by the medical profession. Unfortunately,

the specification made by the government has been so drawn up that the millers have been able to supply a flour without these valuable properties, which is nothing better than the old white flour, so rightly condemned, colored with bran so as to resemble the genuine wheatmeal loaf. The situation has been strongly criticized in the medical press. Sir Ernest Graham-Little (dermatologist and member of parliament) states in a letter to the *Lancet* that the Ministry of Food has extensively advertised the merits of the national wheatmeal loaf and yet its consumption amounts to only 7 per cent of the total bread consumption. Its composition is variable and it cannot be obtained over wide areas. He suggests that one nutritive factor in the increase of tuberculosis (mentioned in previous letters to *THE JOURNAL*) is the poor nutritive value of the white loaf, which is entirely deprived of the wheat germ. He attributes the position to the influence exerted by the milling industry through key positions held by members of it in the ministry.

PARIS

(From Our Regular Correspondent)

Feb. 7, 1942.

Athletics and Youth

In France the development of athletics especially among young people is considered important nowadays. A special Commissariat général à l'éducation générale et au sport has been created, the head of which is Boutra, who won with three other French athletes the Davis Cup in 1928 in the United States. The commissariat has local organizations in each department of France. The physical development of young persons is considered so important that an adolescent desiring to take his bachelor's degree has to pass an examination that proves his athletic qualification. In the schedule of the higher schools for boys from five to twenty-five hours have been devoted until lately to athletic pursuits; for girls it has been three hours a week. The commissariat's immediate program consists in constructing numerous gymnasiums or athletic fields. This activity has been criticized sharply by French physicians because of alimentary difficulties; nowadays all medical problems are regarded from the point of view of the food shortage. At the Academy of Medicine the late Professor Rathery emphasized the danger of excessive athletic activity of the young. He stated three principles to be observed; the constitution of those concerned and the limits of their body capacity, a strict adaptation of the requested charge to this capacity and a prescribed normal feeding. Recently Professor Lesne discussed this problem in detail before the Institut d'éducation physique. The calory requirement for moderate activity is 1,700 at 7 years of age, 1,700 from 7 to 9, 1,900 from 9 to 11, 2,000 from 11 to 12, 2,400 from 12 to 14 and 2,800 over 14. Normally there exists a

Heart Disease in Paris

Year	Deaths from Known Causes, Number	Deaths Caused by Heart Disease Number	Per Cent
1925	38,842	3,975	10.23
1934	30,445	4,515	14.83
1939	27,043	4,050	14.98

calory compensation for adolescents between 7 and 16 years. The organism requires from 900 to 1,500 calories for the support and growth of the body; therefore from 500 to 1,300 calories remain for use against cold and for muscular activity. The cold requires from 200 to 300 calories a day between the ages of 12 and 16 years in rooms having a temperature of 65 F. and 480 to 730 calories in rooms with temperature of 55 F. The caloric loss is less if the child wears warmer clothes. Normal activity at school requires 90 to 300 calories for five to six hours. For one hour of athletic exercise a loss of 200

to 250 calories can be assumed. All this is entirely covered by the caloric value of a normal feeding. The actual feeding, however, grants only a sufficient caloric value until the age of 7 years (1,225 calories). The quantity is insufficient for older children; the deficit for children above 14 years amounts to 1,500 to 1,600 calories a day. Even if the physical education

Deaths in Lyons

Year	Deaths from Known Causes, Number	Deaths Caused by Heart Disease Number	Per Cent
From 1887 to 1891	44,662	3,440	7.70
From 1912 to 1916	38,785	4,877	11.04
From 1927 to 1931	33,180	4,781	12.47
From 1938 to 1940	20,665	3,582	17.32
Last 6 months of 1941	4,663	864	18.52

of young persons is necessary for the normal development of the body, this exercise must be proportional to feeding. If there exists no possibility of providing a normal feeding it is necessary to shorten exercise and prolong rest and sleeping.

On the other hand, excessive activity of young people outside the school has been criticized. At an examination in the Centre d'examen des pilotes civils de la région Lyonnaise Drs. Delaigue and Leonet stated that of 175 candidates between 17 and 20 years of age 22 candidates, that is 12 per cent, proved inapt. These 22 candidates, nearly all athletes, who were examined clinically and by radioscopy, showed signs of cardiac insufficiency. An article entitled "La frénésie sportive et l'usure du coeur" by Auguste Lumière in the November 1941 issue of *L'avenir médical* gives figures on the increasing incidence of heart disease in Paris. The figures for Lyons for half a century also are striking.

On account of the feeding problem the Secrétariat pour la famille et la santé resolved to diminish for the current school year the physical education of children: for boys three hours instead of five, for girls two hours instead of three a week. In several departments the local athletic committees have also reduced play time for rugby, football and other strenuous games.

The Shortage of Medicaments

For months the Academy of Medicine has studied the problem of the increasing shortage of indispensable medicaments. At the suggestion of the surgeon George Duhamel, a member of the Academy of Medicine, a commission has been created which is endeavoring to publish periodically a list of medicaments and chemical products becoming scarce. The commission observes also the consequence of this shortage in medical practice and tries to find substitute medicaments. Fournneau, Tiffeneau, Grosset, Loepcr, Goris, Ramon, Guérin, Duhamel, Rathery and Fabrè (newly elected) belong to this Commission de rationnement pharmaceutique. Most raw materials come from foreign countries, and the importation of these has mostly been cut off. A second reason consists in the difficulty of transportation and the shortage of packing material.

There is also a shortage of surgical material, for instance absorbent cotton, gauze and cellulose. Ether, chloroform and procaine hydrochloride, however, are not scarce. Professor Ramon, scientific head of the Pasteur Institute of Paris, reported that a shortage of vaccines is not to be feared.

In the latest list presented by Goris at a meeting Oct. 21, 1941 of the Academy of Medicine, caffeine, theobromine, bis-muth salts, iodine, camphor, boric acid and its derivatives, petrolatum, quinine, opium and its alkaloids, glycerin, hydrous wool fat, cod liver oil, starch, dextrose, mustard meal, lactose, tartaric and citric acids, insulin, many alkaloids and many chemical and vegetable products were said to be extremely scarce or missing entirely. At the same time the Academy of Medicine published a list of substitutes for these medicaments, the effect of which is of course far less efficacious.

Deaths

Alfred Simpson Taylor * New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1895; at one time instructor and professor of operative surgery and lecturer in neurosurgery at his alma mater; professor of clinical surgery at the Cornell University Medical College from 1910 to 1930; an Affiliate Fellow of the American Medical Association; member of the American Surgical Association, Society of Neurological Surgeons and the American Neurological Association; fellow of the American College of Surgeons; formerly senior attending neurological surgeon at the Neurological Institute; consulting neurological surgeon at the Hospital for Ruptured and Crippled, St. Luke's Hospital, Memorial Hospital for Treatment of Cancer and Allied Diseases, Tarrytown (N. Y.) Hospital and the Overlook Hospital, Summit, N. J.; aged 73; died, January 16, of brain tumor.

Edgar Alexander III * Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1910; member of the American Urological Association and the American Radium Society; fellow of the American College of Surgeons; past president of the Essex County Medical Society; for many years member of the board of education; served during World War I; attending surgeon, St. Michael's Hospital and the Hospital of St. Barnabas and for Women and Children; consultant, Essex County Hospital, Belleville, Rahway (N. J.) Hospital, South Amboy (N. J.) Hospital, Muhlenberg Hospital, Plainfield, Somerset Hospital, Somerville, Perth Amboy (N. J.) General Hospital and the Irvington (N. J.) General Hospital; aged 59; died, February 1, of illuminating gas poisoning, self administered.

George Clute Reid, Rome, N. Y.; Baltimore Medical College, 1902; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; owner and formerly medical director of the Rome Infirmary; on the staff of the Rome Hospital and Murphy Memorial Hospital; member of the board of managers of the Oneida County Hospital; president of the board of managers of the Oneida County Tuberculosis Sanatorium (Broadacres), Utica; aged 63; died, January 8, in Palm Springs, Calif., of multiple myeloma.

Cassie Belle Rose-Thatcher * Boulder, Colo.; Rush Medical College, Chicago, 1914; member of the American Roentgen Ray Society, the Radiological Society of North America and the American College of Radiology; formerly associate professor of surgery (radiology) at her alma mater; for many years radiologist to the Presbyterian Hospital, Chicago; on the staff of the Porter Sanitarium and Hospital, Denver, and the Boulder-Colorado Sanitarium and Hospital; aged 58; died, January 18, of carcinoma of the cervix.

Floyd James Lee * Santa Monica, Calif.; College of Medical Evangelists, Los Angeles, 1924; assistant professor of gynecology at his alma mater; past president of the Santa Monica branch of the Los Angeles County Medical Society; fellow of the American College of Surgeons; aged 43; gynecologist, White Memorial Hospital, Los Angeles; on the staff of the Los Angeles County Hospital, Los Angeles, and the Santa Monica Hospital, where he died, January 3, of coccidioidal granuloma of the mediastinal glands.

George Percy Sprague * Lexington, Ky.; Jefferson Medical College of Philadelphia, 1890; past president of the Southern Psychiatric Association; member of the American Psychiatric Association and the Central Neuropsychiatric Association; formerly on the staff of the Danvers (Mass.) State Hospital; for many years owner and consultant of the High Oaks Sanatorium; aged 78; died, January 18, of subdural hemorrhage resulting from a fall.

Elias Cecil Fischbein * Dayton, Ohio; Cornell University Medical College, New York, 1905; member of the American Psychiatric Association; served during the World War; formerly medical director of the Orchard Springs Sanitarium; on the consultant staff of the Dayton State Hospital; on the staff of the Good Samaritan Hospital and the Miami Valley Hospital, where he died, January 21, of coronary thrombosis, aged 58.

Jesse Herbert Teague, Laurens, S. C.; University of Maryland School of Medicine, Baltimore, 1900; member of the South Carolina Medical Association; past president of the Laurens County Medical Society; served as chairman of the board of trustees of the city schools; aged 69; died, January 5, in the Laurens County Hospital of *staphylococci* septicemia.

Max C. Starkloff * St. Louis; St. Louis Medical College, 1881; past president of the International Society of Medical Health Officers; formerly city health commissioner; past president of the United States Board of Pension Examining Surgeons; in 1918 member of the Volunteer Medical Service Corps, Council of National Defense; aged 83; died, January 15.

Hugh James Downey, Pittsfield, Mass.; Chicago College of Medicine and Surgery, 1912; member of the Massachusetts Medical Society; past president and secretary of the Berkshire District Medical Society; on the staffs of St. Luke's Hospital and the House of Mercy Hospital; aged 59; died, January 31, of cerebral hemorrhage and chronic nephritis.

Filippo Cassola * New York; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1899; aged 66; on the staff of the Mother Cabrini Memorial Hospital; surgeon and president of the medical board of the Columbus Hospital, where he died, February 28, of hepatic cirrhosis with hemorrhage from esophageal varices.

Raymond Robert Westover * Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1906; aged 58; associate surgeon at the Bethany Deaconess Hospital; attending surgeon and chairman of the medical board of the Evangelical Deaconess Hospital, where he died, January 12, of coronary thrombosis.

Martha Maria Brewer Lyon * South Bend, Ind.; Howard University College of Medicine, Washington, D. C., 1907; member of the Association for Research in Ophthalmology; formerly secretary of St. Joseph County Medical Society; aged 70; died, January 18, in the Epworth Hospital of pulmonary tuberculosis.

Edward Rutledge * Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1896; clinical professor emeritus of medicine at his alma mater; for many years physician and surgeon for the city fire department; on the staff of the Roper Hospital; aged 71; died, January 9, of cerebral hemorrhage.

Carl Joseph Harris, Washington, D. C.; University Medical College of Kansas City, Mo., 1900; medical consultant with the Board of Appeals of the Veterans Administration; veteran of the Spanish-American War; aged 65; died, February 22, in the George Washington University Hospital of hypertensive heart disease.

James Francis Cox * Bangor, Maine; Medical School of Maine, Portland, 1909; past president of the Penobscot County Medical Society; served during the World War; aged 61; on the staff of the Eastern Maine General Hospital, where he died, January 18, of gastric hemorrhage.

Henry Reeves Link * Palestine, Texas; Bellevue Hospital Medical College, New York, 1889; past president of the Anderson County Medical Society; formerly county health officer; on the staff of the Palestine Sanitarium; aged 76; died, Dec. 25, 1941, of bronchiectasis.

Joseph Stocking Lewis * Elmira, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1906; past president of the Medical Society of the County of Chemung; on the staff of St. Joseph's Hospital; aged 61; died, January 21, of coronary occlusion and arteriosclerosis.

Robert Millard Deming * Glencliff, N. H.; University of Vermont College of Medicine, Burlington, 1916; served with the British Army during World War I; medical director and superintendent of the New Hampshire State Sanatorium; aged 47; died, January 28, of heart disease.

Frank Downey Travis, Ponchatoula, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1911; member of the Louisiana State Medical Society; aged 57; died, January 5, in a hospital at New Orleans of adenocarcinoma of the rectum and bronchopneumonia.

Stanton Jacob Ten Broeck, Orange, Mass.; University of the City of New York Medical Department, 1893; member of the Massachusetts Medical Society; aged 70; died, January 14, in the New England Baptist Hospital, Boston, of metastatic carcinoma of the pleura.

Oscar M. Richards, Easton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; member of the Medical Society of the State of Pennsylvania; on the auxiliary staff of the Easton Hospital; aged 76; died, January 23, of cerebral thrombosis.

Clinton D. Vermillion, Tescott, Kan.; College of Physicians and Surgeons, Medical Department Kansas City University, Kansas City, 1901; member of the Kansas Medical Society; aged 73; died, Dec. 27, 1941, in Salina of aortic stenosis and coronary sclerosis.

William Blount Turner II ☉ Knoxville, Tenn.; University of Cincinnati College of Medicine, 1924; acting health officer in Anderson County, Ky., from September 1938 to June 1939; aged 42; died, January 10, in Richmond, Ky., of coronary thrombosis.

John Thomas Finley, Prairie du Rocher, Ill.; Eclectic Medical College, Cincinnati, 1927; member of the Illinois State Medical Society; formerly mayor and deputy coroner; aged 44; died, January 25, of malignant hypertension and chronic myocarditis.

Hans Peter Gottfredsen, Lowell, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1906; served during World War I; aged 61; died, January 27, in the Blodgett Memorial Hospital, Grand Rapids, of coronary thrombosis.

Robert Marshall West, Salisbury, N. C.; Medical College of Virginia, Richmond, 1900; member of the Medical Society of the State of North Carolina; on the staff of the Rowan Memorial Hospital; aged 72; died, January 14, of angina pectoris.

Beecher Johnson Terrell ☉ Indianapolis; Medical College of Indiana, Indianapolis, 1894; member of the Indiana State Medical Association; served during World War I; aged 72; was killed, January 14, when his automobile was struck by a train.

Theodore Jacob Ewonchuk, St. Vital, Man., Canada; University of Manitoba Faculty of Medicine, Winnipeg, 1933; aged 35; died, Dec. 19, 1941, in St. Boniface Sanatorium.

William K. Ruble, Wilmington, Ohio; Eclectic Medical Institute, Cincinnati, 1890; for many years county health officer; aged 79; died in January of myocarditis.

William H. Atkinson, Killeen, Texas; University of Tennessee Medical Department, Nashville, 1891; aged 88; died, Dec. 12, 1941, in Waco of senility.

Albert George Webster ☉ Baltimore; University of Maryland School of Medicine, Baltimore, 1911; aged 56; died, Dec. 20, 1941, of carcinoma of the colon.

Albert Frank Streuter ☉ Arenzville, Ill.; Northwestern University Medical School, Chicago, 1906; aged 66; died, Dec. 17, 1941, in Beardstown.

William Medwin Tucker, Long Beach, Calif.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1898; aged 75; died, Dec. 14, 1941.

William Guss Jefferson, Steelton, Pa.; Howard University College of Medicine, Washington, D. C., 1924; aged 43; died, Dec. 21, 1941.

Alan Callender Sutton, Laguna Beach, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1916; aged 49; died, Dec. 4, 1941.

John Carson Halpin, Springfield, Ill.; St. Louis Medical College, 1883; aged 84; died, January 20, of myocarditis.

Edwin S. Wiggers, Cincinnati; Pulte Medical College, Cincinnati, 1895; aged 68; died, January 11, of angina pectoris.

Ivadel Rogers, Pryor, Okla.; Eclectic Medical Institute, Cincinnati, 1898; aged 75; died, January 17, of pneumonia.

Leopold Deutsch, Cleveland; Starling Medical College, Columbus, 1896; aged 73; died in January.

Correspondence

TREATMENT OF HOOKWORM INFECTION

To the Editor:—On page 679 of the February 21 issue of *THE JOURNAL* the question of therapy of hookworm infection is discussed. The answer to the question begins as follows: "The drug of choice in hookworm disease is hexylresorcinol," and a little further down the following statement: "Hexylresorcinol in a single dose will remove 80 to 100 per cent of the parasites. . . ."

I believe that both of these statements are rather misleading and not strictly in accord with the scientific data available. Hexylresorcinol seldom removes more than 70 to 75 per cent of the hookworms present. Occasionally it removes more and often it removes less. It is rather expensive, particularly in view of the fact that hookworm infection occurs in the lower economic groups. Tetrachlorethylene, in general, is much more effective in the removal of hookworms. This drug will remove from 80 to 97 per cent of all the hookworms present; frequently it will remove 100 per cent of the worms. It is much cheaper than hexylresorcinol and has the added advantage that it is a liquid and therefore more easily administered to children.

Having done a large share of the anthelmintic work on hexylresorcinol, I am of course a strong advocate of this drug—especially for ascariasis and mixed hookworm and ascaris infections. I feel however, on a basis of a large experience, that it is not the drug of choice in the treatment of hookworm infection. For additional information on this subject I refer to "Intestinal Parasitic Worms in the United States—Their Diagnosis and Treatment" (*THE JOURNAL*, Sept. 1, 1934, p. 651).

H. W. BROWN, M.D., Chapel Hill, N. C.

SUGAR IN THE DIET

To the Editor:—Now it can be told! Today, when we are confronted by the inestimable nutritional boon of sugar restriction, cannot those who have the health of the nation in keeping, those who have pointed out that some forty million people in this country are not properly nourished, make it plain to the public as a whole that a large role in this deficit of minerals and vitamins is due to the excessive consumption of sugar—refined sugar which supplies energy without any other nutritive assets? The public should be brought to understand that sugar as such is no necessity, that the energy can better be derived from foods that carry other essential nutrients. Even the youngest artificially fed infants today are usually provided with extra carbohydrate in the form of corn syrup.

All those concerned with nutrition have long felt that the excessive consumption of sugar in this country is detrimental to the public health. Whether or not this affects the prevalence and severity of diabetes or the early decay of teeth or other specific disease, the mere fact that almost a quarter of the caloric intake of the nation (and will this estimate be greatly changed if Dr. John Rice's recent demonstration of the waste of 2,500,000 pounds daily in New York City proves true for the country as a whole?) is in the form of sugar makes a sufficiency of B vitamins almost impossible. Numerous reports have demonstrated the paucity of these essential nutrients in the diet in both the United States and Canada. The attempt in peace time to change such entrenched dietary habits has seemed to most workers practically hopeless, especially in view of the tremendous commercial interests concerned. Even the enrichment of refined sugar has been advocated.

But, now, in our peril, faced with the need of sugar for other purposes and of man power in all directions, cannot the nation benefit from an even greater restriction than is now contemplated? Cannot the government further the diversion of sugar crops to other more beneficial ones and find a better use for the men employed in the commercial manufacture and distribution of sweets? Cannot the numerous newspaper food columns make known the superiority of fresh and dried fruits in place of pies, doughnuts, candies, gum and sweetened canned fruits? Cannot the numerous society and moving picture women who want to contribute to the war effort make such desserts fashionable? And may we not plan to keep these benefits in peace time? May we not hope that some of the war time habits develop into permanent tastes if their benefit to the public health is clearly understood? Today, in time of war, every man, woman and child should know that in the restriction of sugar he is not just putting up with an inconvenience, such as foregoing silk stockings or new ice boxes, but is positively contributing to his own health and thus to the strength of the nation.

R. A. GUY, M.D., Boston.

THE de SCHWEINITZ MEMORIAL FUND

To the Editor:—Through the death of Dr. George de Schweinitz in 1938 the medical profession lost one of its greatest leaders, the city a splendid citizen and his many patients a devoted friend. It seems fitting that some permanent memorial be established in Dr. de Schweinitz's name in the University of Pennsylvania, where so much of his life was spent.

With the acquisition of his medical books by the School of Medicine, his friends and former associates plan to equip and furnish a room in the University Hospital to be known as the de Schweinitz Memorial Library. The cost of remodeling such a room, in which his collection of books can be properly housed and which will probably contain his portrait, is estimated at about \$5,000.

When completed, this library will be open to all physicians and medical students and will comprise one of the best collections of ophthalmologic literature in this country.

It is hoped that all his friends will contribute toward the realization of this goal, and the committee will gratefully accept any donation toward this sum, large or small.

EDMUND R. PURVES,
3446 Walnut Street, Philadelphia.

Chairman,
The de Schweinitz Memorial Fund.

"TRAUMATIC" SURGERY

To the Editor:—Pardon this dissertation from one who has repeatedly left himself open to the double charge of being a carping critic and a persistent purist. The present item is evoked by reading papers concerning a branch of the surgical art which is gradually coming into its own, assuming a scientific aspect and is now of special interest—"traumatic surgery."

I wish medical authors could be persuaded not to use tautologic terms. I wonder whether they ever consider the meaning of the word trauma (traw-mah). As I know it, trauma (Gr.) is a wound, an injury, inflicted, suddenly as a rule, by some physical agent. Then how can one justify "traumatic wounds," "traumatic injury" and the like as titles of articles? If I should be asked what other titles should be used I would reply that it is up to the authors, who are supposed to be aware of what they are writing about.

HUBERT A. ROYSTER, M.D., Raleigh, N. C.

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Liability of Employer for Negligent First Aid Supplied by Nurse—On June 2, 1936 the plaintiff was struck in the right eye by a steel chip. He reported the accident to his employer and was directed to a nurse in charge of the defendant's first aid station for treatment. The nurse rubbed the plaintiff's eye with a piece of cotton and, it was alleged, negligently caused the steel fragment to be pressed beneath the surface of the eyeball so that it was not visible from outward inspection and could not be felt by the plaintiff when he moved his eyelid. From June 2 to July 12, 1936, the plaintiff was treated by the nurse, who repeatedly assured him that the eye would soon be all right, that the black spots which he continually saw would disappear and that it was not necessary for him to consult a physician or surgeon. By July 1, 1937, however, the eye had become so discolored and the vision so impaired that the plaintiff consulted physicians underwent an unsuccessful operation for removal of the chip and finally lost the sight in the eye completely. Subsequently the plaintiff filed a suit for damages against the defendant employer contending that the defendant was negligent in causing him to be treated by an unskilled, incompetent person after voluntarily assuming to render medical aid. From an order sustaining the defendant's demurrer and dismissing the complaint, the plaintiff appealed to the Supreme Court of Montana.

The defendant contended that the provisions of the workmen's compensation act were exclusive and that the plaintiff was barred from maintaining an action at law against his employer for damages for an injury arising out of and in the course of his employment. The court held that there was nothing in the act which deprived the plaintiff of the right to bring this action. In the first place, the act was exclusive only so far as accidents arising out of and in the course of the employment were concerned. The injury of which the plaintiff complained was sustained at the defendant's first aid station some distance from the mine and at a time when the plaintiff was not working for the defendant, therefore the injury caused by the negligent treatment by the nurse was not within the terms of the act. In the second place, said the court, the workmen's compensation act did not require an employer to furnish medical aid to its employee. For this additional reason, therefore, the plaintiff was not limited to a recovery under that act. Even though the defendant was not bound to furnish medical assistance for the plaintiff, the court continued, once it undertook to do so it was required to exercise reasonable care in the selection of a competent person to render such assistance and if, through its failure to exercise care and diligence the person selected was incompetent and unskilled and by reason of unskilled treatment the employee or servant was injured the defendant would be liable. In other words, having once accepted the responsibility of furnishing medical attention for the plaintiff, the defendant was under the same obligation as though he had been required to do so by law in the first place. Finally, the Supreme Court held that the plaintiff's cause of action was not barred by section 2909 of the Revised Codes which provides that an employer is not liable for any act in connection with the treatment or malpractice in the treatment of any injuries sustained by an employee. The gravamen of the plaintiff's cause of action, said the court was not based on malpractice in any sense of

the word; it was based entirely on the alleged negligence of the defendant in selecting an unskilled person to treat the plaintiff.

The Supreme Court therefore concluded that the plaintiff's action was not barred by the provisions of the workmen's compensation act and held that the defendant's demurrer should not have been sustained. The judgment of dismissal was therefore reversed and the cause remanded to the trial court.—*Vesel v. Jardine Mining Co.*, 100 P. (2d) 75 (Mont., 1940).

Workmen's Compensation Acts: Refusal of Employee to Submit to Operation.—While fighting a fire in the basement of a home, the plaintiff, a fireman, was exposed to smoke and gas and subsequently developed an inflammation of the trachea and lungs which caused violent coughing. An examination by physicians disclosed that he was suffering from a sub-sternal growth that apparently had been aggravated by the exposure. After being paid compensation for a period of time, the plaintiff submitted to a number of physical examinations by physicians appointed by the industrial commission. These physicians reported to the commission that the plaintiff could be restored to health if he would submit to an operation to remove the growth. The plaintiff refused to undergo the operation, and the commission ordered that compensation payments cease because of such refusal. The order of the commission having been affirmed by the district court, the plaintiff appealed to the Supreme Court of Colorado.

The plaintiff refused to submit to the operation because he was afraid it would prove fatal. He relied solely on the testimony of the physician of the Fire and Police Department, who was his only expert medical witness. That witness stated that he had examined the plaintiff many times and that in his opinion the growth in the plaintiff's neck was a sarcoma, the removal of which might bring on serious results. On the other hand, seven qualified and reputable physicians, appointed by the commission to examine the plaintiff, diagnosed his condition as a sub-sternal nontoxic goiter, not a sarcoma. They testified that this growth could be removed without much difficulty by means of an incision made in the plaintiff's neck. There was some testimony that the necessary operation would be more serious than an appendectomy or an operation for gallstones. The seven physicians were all agreed, however, that, although the operation to remove the growth was considered a major one, the risk involved was no greater than average and the plaintiff's chances of survival were at least 85 per cent. In conclusion, the seven physicians testified that, by means of the operation, the plaintiff could be practically restored as a working unit.

The plaintiff contended that, when an employee relies on the advice of his own physician and refuses to undergo a major operation attended by the hazards of loss of life, his refusal to submit is not unreasonable. The Supreme Court admitted that to be the rule but said that it could not be applied in this case, in the light of the evidence introduced, unless the court was willing to hold as a matter of law that all major operations involve serious risk to life or member. The plaintiff argued that the question of the reasonableness of his refusal to submit to the operation actually was a question of law and that the courts were not bound by the conclusion of the Industrial Commission. Chapter 97, Section 360 (1935 C. S. A.) provided, in part:

If any employee . . . shall refuse to submit to such . . . surgical treatment as is reasonably essential to promote his recovery, the commission may, in its discretion, reduce or suspend the compensation of any such injured employee.

The Supreme Court held that under the foregoing statute the industrial commission was vested with the authority to determine the reasonableness of the plaintiff's conduct. To sustain the plaintiff's contention, the court continued, would nullify that discretion. In view of the great weight of evidence sustaining the commission's holding, the Supreme Court concluded that the discretion lodged in the commission had not been abused and that the claimant should be required to submit to the proposed operation. The judgment for the defendant was therefore affirmed.—*Overton v. City and County of Denver et al*, 102 P. (2d) 474 (Colo., 1940).

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Fourteenth Annual Meeting, Held in Chicago, Nov. 7 and 8, 1941

The President, DR. LAWRENCE D. THOMPSON,
St. Louis, in the Chair

(Continued from page 1004)

Nutritional Macrocytic Hyperchromic Anemia

DRS. CARL V. MOORE and RICHARD VILTER, VIRGINIA MINNICH, M.S., and DR. TOM D. SPIES, St. Louis and Cincinnati: Ten patients with severe degrees of macrocytic hyperchromic anemia and with free hydrochloric acid in the gastric juice have been studied in the Nutrition Clinic at the Hillman Hospital during the summers of 1940 and 1941. In each instance there was a decided shift to younger forms of erythroid elements in the bone marrow, with a striking increase of megaloblasts. All the patients had diets grossly deficient in animal protein, and all but 1 either had or had had clinical manifestations of pellagra. Diarrhea was present in 8. Two had the clinical manifestations of nontropical sprue, 1 was found to have a beef tapeworm and 5 were relieved of their diarrhea when nicotinic acid was given. Eight of the 10 patients were male.

Intrinsic factor was shown to be present in 3 patients. Six responded submaximally when 250 Gm. of raw beef muscle was added to the diet. The meat, however, proved irritating and accentuated the diarrhea in each instance. Five patients were given a diet known to be deficient in animal protein and the B complex. After a control period of one week the crystalline members of the B complex were given both orally and parenterally. There was no change in the reticulocytes, no increase in red cells and no detectable alteration of the bone marrow. An 80 per cent alcoholic extract of beef muscle known to contain extrinsic factor was then given daily, and each patient responded with a reticulocyte rise and at least a slight erythrocyte increase. In several cases this period was followed by one in which the same quantity of beef muscle extract incubated with 100 cc. of normal human gastric juice was given daily; secondary reticulocyte responses were obtained. The parenteral administration of 4 to 10 U. S. P. units of highly purified liver extract given daily after the periods of observation just described produced in 9 cases a significant increase in reticulocytes and an accelerated red cell regeneration. In the remaining case the response had already been maximal.

These observations are interpreted as indicating that (1) macrocytic hyperchromic anemia without acilohrydria occurs not infrequently in regions in the Southern states where pellagra is endemic and (2) the anemia is produced both by a dietary deficiency of extrinsic factor and by poor absorption from the intestinal tract.

DISCUSSION

DR. CHARLES A. DOAN, Columbus, Ohio: I should like to ask Dr. Moore if splenomegaly occurred in any of the cases studied.

DR. FRANK H. BETHELL, Ann Arbor, Mich.: Were tests of hepatic function done in any of these cases?

DR. S. M. GOLDBLUMER, Ann Arbor, Mich.: Four years ago in Atlantic City Dr. Wintrobe gave a paper in which he proposed the theory that yeast is a substance which is similar to the erythrocyte material factor that is present in the liver. I think it has been subsequently shown that absence of the extrinsic factor could produce a similar picture. The extrinsic factor was important not only as to quality but as to quantity. Certain proteins could be administered and would give a response, while others could be administered without any response.

DR. CARL V. MOORE, St. Louis: Splenomegaly was not present in any case. Tests of hepatic function were not performed. In our earlier experiments we used beef muscle rather than brewers' yeast in order to avoid the effect which Dr. Wintrobe noted. In no case have we obtained a reticulocyte response to a daily dose of 200 Gm. of beef muscle when the administration was made to a patient with true Addisonian pernicious anemia. Dr. Goldblumer made reference to the fact that certain proteins apparently possess extrinsic factor activity. The 80 per cent alcoholic extract of beef muscle used in the later experiments was practically protein free.

Clot Retraction Time in Thrombophlebitis and Pulmonary Embolism

DRS. JOHN S. HIRSCHBOECK and WILLIAM L. COFFEY JR., Milwaukee: The clot retraction time, which is the measured interval between the complete formation of the clot and the beginning of its separation from the bottom or the sides of the test tube, was found to be shorter than ten minutes in 9 of 10 consecutive cases of pulmonary embolism. The clot retraction time in normal persons is usually between twenty-five and thirty-five minutes. Patients with thrombophlebitis frequently have a clot retraction time between ten and twenty minutes, but pulmonary embolism did not occur in these patients unless the time became shorter than eight minutes. The clot retraction time is short when the blood sedimentation rate is rapid and the volume of packed erythrocytes in the hematocrit is below normal. A rapid retraction time is most likely the result of an increase in both blood platelets and fibrin together with a lower than normal concentration of erythrocytes in the clot. The administration of heparin in amounts as low as 100 mg. a day has in some cases prolonged the clot retraction time to the normal range for as long as thirty-six hours. In other cases the effect has persisted for only twelve hours.

A rapid clot retraction time may explain why some thrombi, particularly those in postoperative phlebothrombosis, are dislodged so readily soon after formation to become pulmonary emboli. The retraction time becomes shorter than normal during the postoperative period, and if it falls to a level below ten minutes we consider the patient a possible candidate for pulmonary embolism and advise that he be treated prophylactically with small amounts of heparin until the clot retraction time is normal.

DISCUSSION

DR. NELSON W. BARKER, Rochester, Minn.: I should like to ask Dr. Hirschboeck if the clot retraction time remains fairly constant in the patient who has had postoperative thrombosis or pulmonary embolism. I should also like to ask whether he has measured the clot retraction time after operation in a large series of patients and has been able to predict the occurrence of thrombosis and embolism by means of this test.

DR. H. T. RICKETTS, Chicago: I should like to raise the question whether the mere fact that embolism had occurred might have influenced the clot retraction time. Are you able to produce thrombosis artificially in animals and thus lower the retraction time?

DR. JOHN S. HIRSCHBOECK, Milwaukee: In a normal person the clot retraction time, determined several times a week over an extended period, showed little fluctuation. Patients who have manifest thrombophlebitis and who have had episodes of pulmonary embolism may show considerable variations in the retraction time until their final recovery. The effect of heparin on clot retraction as well as on coagulation varies with individuals. Some require more heparin than others. I do not believe that the shortening of the clot retraction time is due to the pulmonary embolism itself, because in 1 case I found it practically as short before the embolism occurred as I did a few hours afterward.

The Use of Pectin Solution as a Blood Substitute, with Special Emphasis on Plasmapheresis Studies

DR. F. W. HARTMAN, VICTOR SCHELLING, DR. HENRY N. HARKINS, BROCK BRUSH and KENNETH WARREN, Detroit: The need for blood substitutes in the present national emergency is manifest. The limitations of whole blood, plasma, serum and acacia are well known. Blood elements are expensive and except in dried form lack preservability. Acacia, on the other hand, combines the disadvantages of forming extensive deposits in the liver with those of antigenic properties. The experimental use of pectin solution as a blood substitute in shock has been made in a series of 80 dogs after extensive bleeding, biliary peritonitis and plasmapheresis. In many of these experiments the blood pressure was maintained and hemoconcentration was prevented for periods of eight hours or more, depending on the dosage. Plasmapheresis was performed with reduction of the plasma protein concentration to as low as 1 per cent. Clinical use has been made of pectin solution in 50 cases, principally as a measure to prevent shock in operative procedures of the type in which blood transfusion had previously been used. The

responses to pectin compared favorably in some instances with those to blood.

Dry powdered pectin is wetted overnight with 95 per cent alcohol. The alcohol is then completely decanted, and cold calcium and magnesium free Ringer's solution is added in the proper amount to make a 0.75 per cent solution of pectin. The solution is stirred vigorously and left standing for three hours. Four cc. of a buffered phosphate solution of pH 6.0 (prepared from 285 Gm. of monosodium acid phosphate and 1,000 cc. of water) and enough 2.5 normal sodium hydroxide are added to each 1,000 cc. of pectin solution to bring the pH to 7.0. This brings the original pH of about 3.0 to 5.5.

DISCUSSION

DR. W. B. COOKSEY, Detroit: In the slides which Dr. Harkins showed after the use of pectin alone, the response in the blood pressure reading was a little slower than is usually seen—two hours. That is certainly slower than is obtained with adequate amounts of plasma. I wonder whether he would amplify this problem and state what the rest of the series showed. I know that Dr. Hartman and his associates have made a study of the toxicity of pectin, and it seems that it is not toxic. However, one must remember that it took physicians a long time to realize how dangerous acacia may be. It seems to me that one should be rather conservative regarding pectin at this time.

DR. E. S. GORDON, Madison, Wis.: I should like to ask whether the authors have made any observations regarding the ultimate fate of the pectin.

DR. HENRY H. HARKINS, Detroit: I will agree with Dr. Cooksey that in the slide referred to the blood pressure showed a slow response to pectin. In some of our other cases this slow response occurred also, but we do have cases in which there was a more rapid response. I can comment on Dr. Cooksey's second remark regarding the nontoxicity of pectin along with Dr. Gordon's question. Dr. Hartman performed experiments on the toxicity of pectin which can be summarized somewhat as follows: 1. Pectin does not seem to be permanently deposited in the liver as is acacia. 2. Pectin is temporarily deposited in the liver, but in dogs killed after three or four days there is no evidence of permanent pectin storage. 3. Pectin seems to be excreted in the urine, and its excretion is more or less quantitatively complete within thirty-six to forty-eight hours.

Sputum Studies in Pneumonia: The Selection of Therapy

DRS. ARTHUR W. FRISCH and ALVIN E. PRICE, Detroit: In a group of 293 cases of roentgenographically proved types I, II, IV, V, VII and VIII pneumonia the specific therapy was selected for each patient by means of sputum examinations. Supportive therapy, or an average dose of 35,000 units of serum, was given to 123 patients whose sputum contained 10 or less pneumococci per oil immersion field. The bacteremic incidence in this group was 11 per cent, and the mortality was 0 per cent. Sulfapyridine or sulfathiazole was given to 130 patients whose sputum contained from 11 to 50 pneumococci per field. The bacteremic incidence in this group was 37 per cent and the mortality rate 6 per cent. Combined chemotherapy and serotherapy was reserved for 24 patients whose sputum contained more than 50 pneumococci per field. The bacteremic incidence in this group was 80 per cent and the mortality rate 54 per cent. In a group of 16 cases miscellaneous therapy was switched from one form to another. The examination of Wright stained smears of rusty sputum proved to be a satisfactory method of differentiating the severe from the mild pneumococcal pneumonia.

DISCUSSION

DR. M. A. BLANKENHORN, Cincinnati: I should like to ask Dr. Frisch if he has made any observations on the presence of antigenic substance or immune body in the circulating blood as compared to its presence in the sputum. Will Dr. Frisch also state what it is that determines the rusty or bloody nature of sputum? What is there peculiar to his selected patients that makes them respond with rusty sputum? I am certain that Dr. Frisch's advice is extremely helpful in the selection of patients for therapy. I am wondering whether by more careful scrutiny of the patients with rusty sputum information perhaps may not be obtained that would be helpful in the treatment of patients who do not have rusty sputum.

DR. OSWALD H. ROBERTSON, Chicago: Since the observations of Drs. Frisch and Price on human pneumonic sputum have gone so far beyond those made by any one else, I can discuss them only with respect to certain analogous observations my associates and I have made in experimental canine pneumonia. We have observed that the severity of the pulmonary infection in the early stages of the disease is reflected in the number of pneumococci present in the bronchial exudate. In the dog with a fulminating infection, great numbers of pneumococci are present and little evidence of phagocytosis is seen. On the other hand, the bronchial exudate of the animal with a well localized lesion in a single lobe exhibits relatively few micro-organisms, and these are all within the phagocytic cells. Thus our observations of experimentally infected dogs would coincide for the first two or three days with those of Dr. Frisch on human beings. However, during the later stages of the canine disease the number of pneumococci in the bronchial exudate tends to diminish substantially, even though the disease may go on to a fatal termination. An exception occurs when new lobes are progressively involved. When following the evolution of individual lobar lesions we have found that the most fluid and pneumococcus rich exudate occurs early in the development of the lesion. After two or three days the exudate becomes thicker and the number of micro-organisms diminishes, probably chiefly as a result of phagocytosis. I should like to ask Dr. Frisch if, in the cases in which he observed many pneumococci late in the course of the disease, spread of the pneumonic process to other lobes was occurring.

DR. ARTHUR W. FRISCH, Detroit: I believe Dr. Robertson has answered Dr. Blankenhorn's question. We use rusty sputum because we are certain that it comes from the lung. Observations similar to those on the sputum have been made on serial smears of the lungs at autopsy. However, in some cases smears from the lungs have failed to reveal the presence of pneumococci, which indicates that the focus is elsewhere in the body. With regard to the relationship of clumping of pneumococci in the sputum and other known immune reactions, we have preliminary data suggesting that this phenomenon is more closely related to the presence of agglutinins in the blood than to the Francis skin test. We are now studying approximately 500 cases and are attempting to correlate the clinical course with the data on the sputum. I did not include type III pneumonia because the outcome in this type is determined by the amount of specific soluble substance produced by the pneumococci and not by the number of pneumococci present in the sputum.

The Effect of Temperature on the Transmission of Lymphocytic Choriomeningitis Virus by Mosquitoes

ALBERT MILZER, PH.D., Chicago: Transmission of lymphocytic choriomeningitis could be effected by *Aedes aegypti* only when mosquitoes of this type were incubated at temperatures ranging between 26 and 34 C.; no virus was detected in mosquitoes kept at 25 C. and lower or at 37 C. Best results in transmission were obtained at 28, 30 and 32 C. and occurred at intervals varying from seven to thirty-eight days following the infective blood meal. These results are not directly comparable to those of Coggeshall because he failed to indicate incubation temperatures in his transmission experiments. The results obtained in the present studies justify repetition of transmission experiments with certain virus diseases suspected of being insect borne, such as poliomyelitis and St. Louis encephalitis, with insect incubation temperatures more carefully controlled than in the past.

DISCUSSION

DR. A. W. FRISCH, Detroit: Did you find any evidence of multiplication of the virus in the mosquito?

DR. CARL G. HARFORD, St. Louis: I think this is a timely paper, especially since investigators from the west coast have reported obtaining the viruses of St. Louis encephalitis and horse encephalitis from mosquitoes caught in their natural environment.

ALBERT MILZER, PH.D., Chicago: No attempt was made to determine whether the virus multiplied in the mosquitoes.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pilonidal Sinus.—Kooistra reviews the literature, data from serial sections of 40 human embryos and 350 cases of pilonidal sinus. Sections of excised tissue were examined microscopically, and a questionnaire was sent to the 202 treated patients to determine the end result. The term pilonidal sinus or cyst is a misnomer, as only about half of the lesions contain hair. Pilonidal sinus is considerably more common than is generally supposed. The 350 lesions were encountered among 313,285 patients admitted to the University Hospital during fourteen years. Seventeen of the lesions were recurrences. The lesion is usually found in patients aged 20 to 25. Of the 350 lesions 258 occurred in males. Symptoms of the lesions developed earlier in the female than in the male patient; 40 per cent of the female patients were less than 20 years of age, as compared to 19 per cent of the male patients. This previously unreported fact apparently is of etiologic significance. Since the human female reaches puberty earlier, it appears that these lesions are activated by the sex hormones. The disease is restricted to the Caucasian race. A questionnaire study of the family history of 100 representative patients revealed a hereditary factor in 10 per cent. Evidence indicates an Anlage for this defect in the earliest stages of embryonic development. In 32 per cent of the patients there was a definite history of trauma, but in only 14 per cent did it occur within a month of the onset of symptoms. A study of associated and incidental diseases revealed that 4 patients had mental disorders, 6 skeletal congenital defects, 4 inguinal hernias, 4 diabetes, 6 pulmonary tuberculosis, 1 osseous tuberculosis, 3 syphilis, 7 associated hypertension, 3 nephritis, 3 arthritis and 2 furunculosis. Pain (in 84 per cent) and discharge (in 78 per cent) due to infection were the predominating symptoms. Recurrent abscesses and draining mid-line sinuses in the sacrococcygeal region were observed often. Of the 202 patients treated at the University Hospital, 117 had

had previous operative procedures. The pathologic picture is that of a dermal sinus with hair in about half the cases. All the sections showed evidence of acute or chronic inflammation. Treatment remains an individualized problem. Incision and drainage are indicated for any acute manifestation. The use of Carnoy's solution after incision has merit in selected cases. Excision with primary closure is advisable for the uninfected and the less extensive lesion. Excision and open packing are indicated for the more severe and the recurrent lesion. A prolonged healing time and recurrence are common problems of treatment. Replies to a questionnaire received from 89 patients whose lesion was excised reported "permanent cure" in 74 per cent. Data on patients in whom dye was used preoperatively favor its use to delineate the lesion.

Surgery of Thyroid.—Heyd states that whatever the etiologic factor or factors might be in hyperthyroidism the disease is not a single condition. It may manifest itself in a variety of clinical pictures with different pathologic entities. The indications for surgical intervention depend on the clinical manifestations, pressure symptoms and malignant changes. Overdosage and continuous administration of iodine preparations are to be discouraged. Iodine does not cure goiter; it aids preoperative treatment, controls symptoms and is of great value in crisis. The incidence of cancer of the thyroid is fairly constant, and if every patient with a nodular goiter is considered as a candidate for surgical intervention the incidence may be decreased. Good results are the rule in cardiac disabilities that are the result of toxic adenomas. In exophthalmic goiter surgical intervention is only one phase of treatment; a proper medical regimen and control of symptoms for not less than a year post-operatively are equally important. The basal metabolic rate is but one sign of hyperthyroidism, and it should never be over-emphasized. Vocal and respiratory difficulties that follow thyroidectomy are still a pressing problem to even the most expert surgeon.

Hypoxia.—Batten points out that most instances of hypoxia that occur in the operating room are the result of nitrous oxide anesthesia, which is the lightest anesthesia unless metabolic depressant drugs are used as adjuvants. The plane of anesthesia may be deepened through the diminution of oxygen the patient is permitted to breathe. When the concentration of oxygen in the inspired atmosphere is permitted to drop to less than 20 per cent the procedure should be termed asphyxia. When more relaxation is demanded than can be obtained by an 80 to 20 per cent nitrous oxide-oxygen mixture, the nitrous oxide should not be increased at the expense of oxygen but some more potent agent should be employed. Also hypoxia in the operating room at times arises from the injudicious use of pain relieving drugs, obstruction to a patent airway, deep Trendelenburg position, sharp angulation of the table in operations on the kidney, use of the gallbladder rest, persistent laryngospasm and spinal anesthesia, which decreases the oxygen in alveolar, arterial and venous systems. The author believes that attention to the following six factors will diminish the number of anesthetic accidents: (1) the avoidance of the promiscuous use of respiratory depressant drugs, (2) the avoidance of giving nitrous oxide in a concentration of less than 20 per cent of oxygen, (3) the disturbance of the patient's physiologic condition as little as possible, (4) the protection of the patient on his return to bed against aspiration of mucus and vomitus and from asphyxia from a relaxed tongue, (5) the administration of oxygen to any patient exhibiting signs of hypoxia in the operating room and (6) the avoidance of routine spinal anesthesia.

Natural History of Experimental Poliomyelitis Infection.—Sabin and Ward studied the spread of poliomyelitis in the central and peripheral nervous systems of 8 rhesus monkeys. They injected the M. V. virus into the sciatic nerve, collected nasal secretions on plugs of absorbent cotton every twenty-four hours during life, pooled the secretions collected from several monkeys and tested them for the virus. Tissues of animals dead from the disease were studied to ascertain the extent of the centrifugal spread of the virus. The incubation period was relatively short: paralysis was observed first on the third day in 3 monkeys, on the fourth day in 4 and on the fifth day in 1. The first rise in temperature occurred on the same day as the paralysis in 6 monkeys and on the day preceding the paralysis in 2. The appearance of paralysis first in the inoculated leg of 6 monkeys and in both legs of 2 is in accord with the usual course of the disease. The disease was permitted to run its full course to allow the greatest possible spread of the virus. The virus was not demonstrable in the nasal secretions of the infected rhesus monkeys during any stage of the preparalytic or the paralytic phase of the disease. Sabin's and Ward's observations indicate that by the time the terminal phase of the disease is reached the virus had not spread sufficiently either in the central nervous system, to involve the olfactory bulbs and the adjacent nasal mucosa, or peripherally, to affect the collateral sympathetic ganglions or the nerve cells of the parasympathetic system, the salivary glands and the pharyngeal wall about the tonsils. The negative results with the tonsils offer confirmatory evidence for the absence of the virus in the tissue spaces of the nasal mucosa and other regions whose lymphatics drain into these nodes. The finding of virus in the spinal cord of each monkey lends weight to the negative results with other tissues. Under certain circumstances (different from those of the present study) the presence of virus in these ganglions and tissues may be used as an index to the point of entry of the virus.

Pyridoxine for Paralysis Agitans.—Meller gave pyridoxine to 4 patients with postencephalitic and to 6 with idiopathic paralysis agitans. The patients were relief clients whose diets could have been deficient; they were given also brewers' yeast and cod liver oil tablets. Previous experience with these substances had no specific therapeutic effect. Pyridoxine was given daily in a dose of 50 mg., subcutaneously or intravenously, for ten days; then the dose was increased to 100 mg. for three or four days. The dose was then continued or decreased, depending on the patient's response. The patients responded promptly by improving to a degree beyond which even larger doses brought no benefit. After this improvement had been attained the patient was given 50 mg. subcutaneously on alternate days. As a partial control, 3 similar patients were treated with physiologic solution of sodium chloride; 1 thought that he felt better, but none showed any objective change. Only 1 of the 10 patients failed to respond in some measure. The improvement in the others consisted of a feeling of relaxation, decrease of spasticity and disappearance of pain and an increased feeling of well-being. Although no objective change in tremor was noticeable, the patients reported that they had better control of their muscles (the arms and legs moved with more assurance, and the tremor was not so annoying).

Pyogenic Infections.—Grodinsky states that of the three major types of pyogenic infections of the hand (lymphatic, fascial and tendon sheath) acute lymphatic infections are most dangerous to life but the least likely to lead to permanent disability. The main principle in their treatment is to avoid incision before the infection has become localized. Permanent disability from infections of the tendon sheath may be reduced to a minimum by early and adequate surgical treatment. Likewise in infections of the fascia early and proper surgical treatment should prevent permanent loss of function.

Exanthematic and Endemic Typhus.—Findlay reports the accidental infection of 2 laboratory workers with endemic typhus during work with active endemic typhus rickettsias. The infection in 1 worker more than 40 was apparently modified because of the presence of some degree of immunity against exanthematic typhus in contrast to the other worker, who was 18. This unrehearsed human experiment, the author believes, bears out the contention that there is a close antigenic similarity between the rickettsias of exanthematic and endemic typhus.

Brachial Neuritis in Epidemic Form.—Wyburn-Mason discusses the occurrence of brachial neuritis in 42 patients within eight months. The patients were between 30 and 77 years of age. The epidemic began in the winter and persisted into the spring and the summer. The clinical features (pain, burning and tenderness in the region of the cords of the plexus and over the ulnar nerve, sensory changes and motor weakness) suggest that the anterior primary divisions of the spinal nerves from the third cervical to the fourth dorsal inclusive, in whole or in part, were involved. Usually the upper part of the plexus, and the skin segments served by the fifth and sixth cervical nerves, were affected; but careful examination also revealed sensory changes of a wider distribution. The tendon reflexes in the affected limb were usually increased or decreased. The severity of the disorder varied from patient to patient. The ultimate outlook is good, and the milder types of neuritis improve soon, but the more severe ones have so far been refractory to treatment. The similarity of the disorder in all the patients suggests that the condition is the result of an infection and that the site of the lesion is in the nerves at a point distal to the posterior primary divisions. The cause is not known, but

it seems to be a clinical entity, possibly the result of a heretofore undescribed infection appearing for the first time in this war. No patient frequented public air raid shelters.

Sulfapyridine in Filariasis.—Earle cites 3 further cases of lymphadenitis complicating filariasis successfully treated with sulfapyridine. The striking beneficial effect of sulfapyridine on the lymphadenitis probably indicates that the complication is due to secondary streptococcal infection rather than to the filariasis itself. The number of microfilariae in the blood stream is not reduced by the drug.

- *Epidemic Myositis, with Neuritis, Erythema and Meningeal Symptoms. D. Williams.—p. 283.
*Simmonds' Disease or Panhypopituitarism (Anterior): Its Clinical Diagnosis by Combined Use of Two Objective Tests. R. Fraser and Patricia H. Smith.—p. 297.

Epidemic Myositis.—Williams reports the occurrence in 5 men of the Royal Air Force in the early summer of 1940 of a previously undescribed syndrome: an acute febrile illness with symptoms and signs of myositis and meningitis. The syndrome occurred at one station only and followed inoculation with tetanus toxoid and T. A. B. vaccine. The syndrome did not develop in thousands of other recruits similarly inoculated. In addition to the syndrome, 4 of the 5 patients had involvement of the peripheral nerves, 3 had an erythematous rash and 3 had visual disturbances. All the patients recovered completely, and no causal agent could be isolated. It is suggested that the syndrome was probably caused by a virus which may have been activated by the T. A. B. inoculations. The illness began within forty-eight hours of the inoculation and lasted for less than a week. In 1 patient it was complicated by acute gastroenteritis and in another 1 by a pleural effusion. The sterile cerebrospinal fluid of 3 men contained an excess of lymphocytes and polymorphonuclear leukocytes. All other investigations gave negative results.

Simmonds' Disease or Panhypopituitarism.—Fraser and Smith used the insulin tolerance test and a urinary 17-ketosteroid assay for 10 patients to distinguish Simmonds' disease, or panhypopituitarism, from anorexia nervosa and myxedema. The tests furnish a reliable and objective method for diagnosing Simmonds' disease during life. The tests were applied to 15 other patients with allied syndromes or less definite pituitary defects: primary myxedema and anorexia nervosa. In the 10 patients with panhypopituitarism the insulin tolerance test gave a characteristic curve: after a normal initial fall of blood sugar there was a failure or a delay in the usual spontaneous return. The response to epinephrine was usually abnormally slight but varied in accordance with the degree of hypoglycemic unresponsiveness (insulin hypersensitivity), that is between 80 and 47 per cent. To a certain extent it appeared that the degree of failure in the return of the blood sugar corresponded to the clinical degree of pituitary failure. Similar abnormal insulin tolerance curves may be found in hyperinsulinism and Addison's disease and possibly with severe hepatic disease or malnutrition. The urinary 17-ketosteroid assay, with one exception, was zero (less than 0.5 mg. in twenty-four hours). At least two assays were done for each patient. The only universal symptoms of the 10 patients with panhypopituitarism were hypogonadism and asthenia; the only universal signs, other than those of hypogonadism, were some cutaneous atrophy and loss of most or all of the axillary hair. The basal metabolic rate was low but the serum cholesterol often high. Four of the 8 patients with anorexia nervosa gave a normal reaction to the insulin tolerance test and 3 one similar to that found in panhypopituitarism, and in the 3 patients with primary myxedema the test showed a slow initial fall or insulin resistance. The 17-ketosteroid assays on 4 of the patients with anorexia nervosa gave results ranging from 2.7 to 14.7 mg. in twenty-four hours. These 4 patients were those with a reaction to the insulin tolerance test indistinguishable from that seen in panhypopituitarism. The assays of the patients with primary myxedema varied from zero to 1.7 mg. It is concluded that by the combined use of the two tests panhypopituitarism (anterior) producing even fairly mild symptoms can be distinguished from allied syndromes.

Action of Toad Venom on Bleeding Time.—Derouaux points out that extract of the parotid gland of the toad has been recommended for treatment of hemorrhage. The presence of epinephrine in the preparation seems to justify this. Having verified the favorable influence of the medulloadrenal hormone on the bleeding time, the author decided to submit to experimental control the action on the bleeding time of bufotalin, bufotenin and epinephrine, administered in the form of a total extract. He found that, in spite of the presence of epinephrine (extremely small quantity), besides the bufotalin and bufotenin, the total extract of the parotid gland of the toad (*Bufo bufo*) does not exert any hemostatic action in rabbits. On the contrary, in relatively large doses (1 cc. of a 1:30 solution) toad venom strongly impedes the mechanism of spontaneous arrest of hemorrhage.

New Modified Typhoid-Paratyphoid-Tetanus Vaccine.—Hallauer and Regamey point out that Ramon's typhoid-paratyphoid-tetanus vaccine has the disadvantage of eliciting local and general reactions and of impairing the work capacity for one or two days. In the presence of allergy, vagotonia, rheumatism or tuberculosis it may produce complications. These disadvantages may be obviated by substituting, for the customary bacillary suspensions of typhoid-paratyphoid, endotoxoids that have been detoxified by solution of formaldehyde. The composition of 1 cc. of such a modified triple vaccine is as follows: 0.66 cc. of tetanus toxoid and 0.33 cc. of *Salmonella* endotoxoid (treated with solution of formaldehyde) corresponding to 1,600 millions of typhoid bacilli, 1,200 millions of paratyphoid B schottmüller bacilli, 600 millions of paratyphoid B Breslau bacilli and 600 millions of paratyphoid A bacilli. The efficacy of this vaccine was compared with that of Ramon's combination vaccine in guinea pigs and in human subjects. The modified vaccine was as effective against tetanus and *Salmonella* infections as Ramon's original vaccine. It is less toxic and causes milder reactions, yet the antibody titers of the persons vaccinated with it are as high as those of persons inoculated with Ramon's vaccine.

*Cancer of Prostate, Acid Phosphatase of Blood Serum and Castration. L. F. Ajamil.—p. 333.

Cancer of Prostate.—Reports in American literature and Ajamil's own observations suggest that acid phosphatase in blood serum is greatly increased in all cases of carcinoma of the prostate with metastasis to bone. The metastatic spread of the tumor can be surmised from the level of acid phosphatemia, even if the metastasis cannot be visualized by roentgen examina-

tion. The development of metastasis to bone in cancer of the prostate is stimulated by acid phosphatases in the blood serum, the increase or diminution of which is controlled by the testicular hormones. Effects of testicular hormones on the acid phosphatase of blood serum and the relation between acid phosphatase in the blood and metastasis to bone is demonstrated by the fact that castration or continued administration of estrogens causes diminution of acid phosphatemia, with a parallel improvement in the general condition of the patient and a diminution of symptoms of metastasis to bone, whereas administration of androgens aggravates the symptoms and increases the acid phosphatemia. Cosmetic bilateral castration is the operation of choice. It is performed with the patient under local anesthesia and consists in opening the tunica albuginea, removing the testicles and injecting a small amount of sulfanilamide within the empty scrotum and suturing without drainage. A small hydrocele, of about 30 cc., replaces the testicle. The operation controls the spread of the bone metastasis and improves the general condition of the patient. Whether the hydrocele will be permanent remains to be seen.

Tuberculous Reinfection in Children and Adults. J. Peña Cereceda and M. Felman.—p. 791.

Centers of Ossification in Diagnosis of Rickets.—Schwarzenberg and his associates aimed to determine the diagnostic value of tardiness in appearance and development of centers of ossification in rickets. On the basis of their clinical observations they concluded that rickets retards the appearance of centers of ossification in direct relation to the intensity of the disease. The absence of carpal centers before the tenth month of life is of no value for the diagnosis of rickets. After ten months its value is relative and should be judged together with the rest of the symptoms. The defects in the structure and size of the centers of ossification have diagnostic value at any age. Certain dystrophies seem to be the cause of the retarded appearance of nuclei of ossification. In cases in which the diagnosis is doubtful the vitamin "push" test (administration of a single large dose of vitamin D) is frequently capable of clarifying the cause of the absence or the defective structure of the centers. The sudden and disproportionate appearance of centers or the increase in ossification fortifies the roentgenologic diagnosis of rickets.

*Tuberculosis of Bones and Joints. A. Wittek.—p. 745.
Endometriosis of Urinary Bladder. K. Henning.—p. 750.

Tuberculosis of Bones and Joints.—Wittek observes that children with tuberculous spondylitis may cry out at night and complain of abdominal pains, or of pain in the knee. Peculiarities in walking, avoidance of bending and turning and Baeyer's symptom are significant. These signs, however, may be produced by lesions other than tuberculous ones. Roentgenologic examination of the spine may give negative results in the early stages of tuberculous spondylitis. Differentiation of tuberculous spondylitis from other spinal disorders, such as osteomyelitis, typhus spondylitis, lymphogranulomatosis, gumma and tumor metastasis may be difficult. The possibility of military dissemination and of the development of tuberculous meningitis makes the prognosis grave. Fistula formation is an unfavorable sign. Tuberculosis of bones and joints is not a local process but a manifestation of a generalized process. For this reason the treatment must be general. Conservative treatment, with emphasis on fresh air and heliotherapy, has given good results, but long duration is one of its disadvantages. The author recommends conservative treatment for growing patients whenever possible and resorts to surgical intervention only in exceptional cases. Thus he may remove a juxta-articular focus to avoid perforation into a joint. Resections are never done for children, but for adolescents arthrodesis of the hip joint may be done to hasten recovery. For adults surgical treatment is employed (1) to save life or (2) to reduce the duration of the treatment.

Book Notices

The Hospitals Year-Book, 1941: An Annual Record of the Hospitals of Great Britain & Ireland Incorporating "Burdett's Hospitals & Charities," Founded 1889. Issued under the auspices of the Joint Council of the Order of St. John and the British Red Cross Society and the British Hospitals Association (Incorporated). Sub-Editor: A. E. Ceadel, F.S.S. Cloth. Price, 22s.; \$4.40. Pp. 299, with illustrations. London: Central Bureau of Hospital Information, 1941.

The Hospitals Year-Book is a classified directory of hospitals and related institutions throughout Great Britain and a compendium of knowledge on hospital topics. The directory section presents names, addresses, persons in charge and, with the use of symbols and columns, a truly amazing amount of useful information about hospitals and related institutions in Great Britain and overseas. Separate directories include voluntary hospitals, municipal hospitals, maternity hospitals and homes, mental hospitals, institutions for the chronic and incurable, and convalescent hospitals and rest homes. There also is a long list of contributory schemes and funds, and names of examining bodies. The service of the British hospitals in war times is well outlined by authoritative descriptive articles on the bombing of hospitals (illustrated), war shelter hygiene, regionalization of hospitals, financial review of voluntary hospitals and the future of voluntary hospitals. There is much information of special interest to hospital administrators, ranging from purchase tax to road traffic accidents. This issue of the Year-Book contains many features of special interest and help to Americans who are connected with the service of hospitals in defense and their protection.

Standard Bodyparts Adjustment Guide: Traumatic Cases, Occupational Diseases, Disability Evaluations, Medical Fees, Statutory Digests. Fabrikoid. Price, \$15, including ten years' revision service. No pagination, with illustrations. Chicago: Insurance Statistical Service of North America, 1941.

This loose-leaf manual, compiled by the Insurance Statistical Service of North America, will strike many physicians and others as a particularly convenient compilation of a great many clinical and administrative aspects of disability evaluation and accident and disease indemnification. The material is not designed to appeal to physicians alone and, indeed, many of the anatomic charts and much of the medical data presented are directed at interested nonprofessional groups, and of these principally insurance adjusters. In case of troublesome appraisal of working or earning power after accident or disease, the physician will still be obliged to consult the more extended and standard reference works in this field. The discussion of fees contained in this book can be studied with profit by nearly every physician who comes in contact with compensation problems. The method employed is to list in parallel columns the minimum, maximum and mean average fees for specific medical procedure, including those established for laboratory, x-ray, dental, special consultation and after-care. Subject matter is drawn from fee schedules adopted in eighteen widely diversified states. To be sure there are two schools of thought about fee schedules, the serious objection being that minimum rates tend to become fixed as maximum, no matter how much extra care or skill has been necessary in the unusual or refractory case. Nevertheless, since three levels of fees are included, dependable listings of this kind may be useful in combating the insurance organizations which habitually shave fees because the income is certain or which habitually shop around for the cheapest available medical service. Other helpful sections of the book cover the occupational diseases, listing the character of exposure and symptomatology and a final summarization of the workmen's compensation and occupational disease acts of all American jurisdictions. Here again the data are conveniently arranged for ready reference and appear dependable enough for all ordinary purposes. If information in greater detail is required, recourse had better be taken to official documents. For example, it is indicated that Michigan has no rules or regulations relating specifically to compensation for hernia. Actually, hernia is listed in the schedule of occupational diseases in that state.

You Too Can Have a Baby (A Plan for Parenthood). By Abner I. Weisman, M.D., Adjunct Gynecologist to the Jewish Memorial Hospital, New York. Foreword by Dr. Max Huhner. Cloth. Price, \$2. Pp. 256, with 14 illustrations. New York: Liverlight Publishing Corporation, 1941.

The author states that his purpose in writing this book is to help couples who wish to have a baby and are unable to of their own volition, to elevate the standards of education regarding sex and fertility, to correct many myths and much misinformation and to provide a source book for the layman who is interested in the problems of fertility.

The first thirteen chapters of the thirty-four in the book deal with the anatomy and physiology of reproduction, fertilization, pregnancy, confinement and labor. There are some inaccuracies in the text which should be corrected in the next edition. For example, on page 44 the author states that "medical authorities are of the opinion that the two ovaries alternate each month in expelling eggs." On page 88 he states that the breaking of the "waters" is the forerunner of the real labor, whereas often the membranes do not rupture until the end of the first or second stage of labor. On page 85 he states that intercourse should be refrained from "almost completely" in the last two months of pregnancy, and on page 105, in instructions to the prospective parents, he writes "during the last month of pregnancy, sexual intercourse is forbidden."

Chapters 14 to 19 deal with sterility and its causes, with a discussion of the examination of both husband and wife, including the methods of examination of the semen and essential tests for the wife. Chapters 19, 20 and 21 deal with the treatment of sterility, including instructions to the couple as to the optimum time for intercourse and methods which may be found helpful. The author then discusses venereal diseases and sterility, habitual abortion, ectopic pregnancy and sterility following stillbirths. On the last named subject he states that erythroblastosis fetalis is not likely to occur with a subsequent baby. This is contrary to the accepted belief. The last chapters deal with artificial insemination with semen from the husband or a donor, the medicolegal aspects of artificial insemination, adoptions and the social aspects of the barren couple.

While the problem of sterility is vitally interesting to many childless couples, and while this book is a contribution toward their help, it is not completely satisfactory for its purpose. The title is misleading, as the author himself states that only a portion of the sterile couples in this country can be helped, by scientific means, to have a baby.

Eagleton's Index and Abstracts of Literature on Progress in Intracranial Lesions Related to Aural and Nasal Conditions. Published in *Archives of Otolaryngology*, 1925, 1926, 1927, 1928, 1929, 1932, 1937, 1940. Published for Gratiuitous Distribution to American and British Otolologists in the Interest of Anglo-American Unity, and to Commemorate the Enactment of the Lend and Lease Law—"a New Magna Carta" of Democracy's International Cooperation, by Wells P. Eagleton. Edition limited to 1,000 copies. Paper. Various pagination, with 2 illustrations. Newark, N. J., 1941.

For fifteen years the author abstracted literature pertaining to advances in the knowledge of intracranial states in relation to conditions of the ear, nose and throat. The first half of this volume is an assembly of the author's thoughts or facts concerning these numerous contributions. The other half of the volume comprises a reprinting of papers by Dr. Eagleton which have been published in the *Archives of Otolaryngology* during the last several years. The author is distributing this edition gratuitously to American and British otologists in the interest of Anglo-American unity. His aim also is to make accessible to sincere workers in this field a compilation of recent literature on borderline subjects pertaining to otology or rhinology and to neurology or neurosurgery, a field in which the author is internationally known.

The Toxemias of Pregnancy. By William J. Dieckmann, M.D., Associate Professor of Obstetrics and Gynecology, The University of Chicago. Chicago. Cloth. Price, \$7.50. Pp. 321, with 53 illustrations. St. Louis: C. V. Mosby Company, 1941.

The toxemias of pregnancy are probably as old as medicine itself. The author's monograph is a testimonial not only to the important advances that have been made in the field but also to our lack of knowledge. Dieckmann has exhaustively considered every aspect of the subject and has included his own

extensive studies as well. He points out the numerous controversial factors which make the problems involved so perplexing and attempts to correlate the chemistry, pathology, physiology, pharmacodynamics, hormones and constitution according to their places in the field. With minor exceptions he has carefully presented practically all of the work that has been done up to now. The most important chapter in the book is that on physicochemical determinations. The material is exceedingly complicated and this probably explains why so few obstetricians per se have made contributions to the subject. A good part of the research that is taking place is in the hands of the chemists and internists, and although this is entirely justifiable it suggests that much more may be accomplished if these workers could be combined as a team. The monograph is deserving of the highest praise. The author has presented his subject clearly. Numerous charts, graphs and case reports illustrate his careful conclusions. The chapter on treatment is excellent. It is recommended to the entire profession, but to the obstetrician it should prove invaluable.

Venereal Diseases. By E. T. Burke, D.S.O., M.B., Ch.B., Director of L. C. C. (Whitechapel) Clinic, London. Cloth. Price 30s. Pp. 549, with 141 illustrations. London: H. K. Lewis & Co., Ltd., 1940.

As is customary in many of the European countries, this volume is devoted not only to syphilis but also to gonorrhea, trichomonas infections, chancroidal infections, paradenitis (lymphogranuloma venereum) and granuloma inguinale. Most of the comments on the volume will be limited to the subject of syphilis.

As the author himself states, many of the opinions are at variance with general teaching. For example, this is true of the lipid concept of syphilis and of the mode of action of arsphenamine and bismuth and of the evaluation of antisyphilitic therapy. Unfortunately, space does not allow discussion of these, particularly of the first, which is at least a thought provoking approach to syphilis and its spread in the body. He divides syphilis into acute and chronic stages. Under the former one finds first degree, seronegative type; second degree, seropositive type; third degree, general secondary type, and fourth degree, up to complete disappearance of the secondary manifestations. Under chronic syphilis there are fifth degree, endosyphilis (latent syphilis); sixth degree, tertiary, cardiovascular and visceral, including neurosyphilis; seventh degree, neurosyphilis including meningeal, and, eighth, prenatal syphilis.

Burke is a firm believer in the use of continuous therapy as advocated generally in this country. Moreover, he is a strong proponent of fever therapy in central nervous system syphilis and in certain types of gonococcal infection. While he elaborates a rather formidable method of estimating antisyphilitic compounds in terms of therapeutic units, on the whole his end results and recommended dosages are quite acceptable. He does not think that bismuth and arsenic have a direct spirocheticidal action. He does not recommend bismarsen, and he believes that acetarsone has a much lower therapeutic action than arsphenamine. He is a great believer in the use of the liposoluble bismuth as the bismuth compound of choice in the treatment of syphilis. He thinks that intraspinal therapy for central nervous system syphilis is "obsolete and unsound." He still thinks that there is a place for Zittman's decoction in malignant syphilis. The author believes that myocarditis may be encountered even in early syphilis and completely accepts Warthin's teachings. Moreover, in his opinion pulmonary syphilis is more common than is generally supposed.

It is noted that throughout the book the word "gland" is incorrectly used for lymph node. On page 74, ninth line from bottom of page, the word "trauma" is misprinted. On page 311 the statement is made that "the cord blood should always be taken and a positive result here means syphilis in both mother and child." This is certainly not accepted in all cases in American practice, nor do we believe it to be the case. The reviewer cannot agree to the value of the nostrum Psorimangan in lymphogranuloma venereum, or to satisfactory results in this disease from the use of fuadin.

Burke's treatment of the subject of central nervous system syphilis is particularly satisfactory and would be of profit for any man to read who is interested in this particular subject.

While the author's opinions on various phases of syphilis are perhaps not generally acceptable, at least they are stimulating and provocative of independent thinking. The book is to be recommended to the reader desirous of getting a fresh slant on the subject of syphilis, but some of the six colored plates are rather poor. Many of the photographs are excellent, others poor. The binding is adequate. Moreover, there is a good working index.

A Long Term Study of the Experimental Neuroses in the Sheep and Dog with Nine Case Histories. By O. D. Anderson and Richard Farmer. Published with the Sponsorship of the Committee on Problems of Neurotic Behavior, Division of Anthropology and Psychology, National Research Council, Washington, D. C. Psychosomatic Medicine Monographs Volume II, Nos. III and IV. Paper. Price, \$3.50. Pp. 150, with 36 illustrations. Washington, D. C.: National Research Council, 1941.

In this monograph are presented data and conclusions regarding experimental neuroses in sheep and dogs. The manifestations of neuroses in the animals used, the procedures precipitating them and the therapeutic procedures influencing them are discussed. The discussion is broad and the conclusions are conservative. "In summary, the working hypothesis here advanced is concerned with a circle of connected events. Repeated and prolonged emotions, incident to the experimental procedures, produce a chronic imbalance of the internal secretions which induce a constant state of imbalance of the chemistry of the nerve cells. A change in the irritability of the nervous system results. The nervous system may become hyperirritable. Further and prolonged stimulation of the emotion reinforces and perpetuates the changes in internal chemistry and the vicious circle of events is complete."

A New Test for the Detection of Colorblindness. By P. B. Willberger, B.Sc., M.Sc., M.D., Medical Examiner, Civil Aeronautics Administration, U. S. A. Boards. Price, \$8. Pp. 22, with 19 plates. Columbus, Ohio: Warner P. Simpson Co., 1941.

The author believes that the Ishihara test, now in common use for color blindness, is mainly a test of color "intensity" and cannot be entirely relied on. He presents an objective test consisting of a set of plates made up of nonfading color "chips" of high chroma, high value and accurate hue. The subject need not know the name of a single color. The test is based on the fact that when one gazes at a given color for an appreciable length of time and then shifts the gaze to a blank sheet of white or neutral gray paper the complementary color will appear on the paper as an "after-image" and will be of the same size and shape. The tests can be easily made but will fail in a certain percentage of cases because of lack of concentration on the part of the subject tested. The price of the book seems entirely out of line with the contents.

The Autonomic Nervous System: Anatomy, Physiology and Surgical Application. By James C. White, M.D., Assistant Professor and Tutor in Surgery, Harvard Medical School, Boston, and Reginald H. Snellwick, M.D., Instructor in Surgery, Harvard Medical School. Second edition. Cloth. Price, \$6.75. Pp. 469, with 92 illustrations. New York: Macmillan Company, 1941.

This edition of Dr. White's monograph has been extensively rewritten and expanded. It is a refreshing and gratifying experience to read about the autonomic nervous system as a living, dynamic, functioning apparatus. The subject is so treated largely because the authors are not anatomists or physiologists but clinicians dealing with actual disturbances in living human beings. In this book the reader may find the latest facts and theories in proper perspective. There are excellent discussions of clinical syndromes and surgical procedures. The book is written interestingly; it is well illustrated and excellently documented with carefully chosen references. The book is a necessity for the library of the physician as well as of the specialist.

Hospital Ballads. By Frederick E. Keller, M.D. Cloth. Price, \$1. Pp. 43. Philadelphia: Dorrance & Company, Publishers, 1911.

This is a collection of poems covering everything from the lofty hospital building to the lowly tonsil. Many are on the serious side and thought stimulating; some, however, provoke unexpected and delightful chuckles. Doctors especially should enjoy this book immensely, finding in it parallels to many of their own impressions and experiences.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

SENSITIVITY TO SOAPS

To the Editor—A married woman aged 45 became sensitive six months ago to certain soaps, flakes and chips which she used in the course of her washing about the house. After using these soaps she would have severe attacks of lacrimation, sneezing, profuse rhinorrhea and stuffing of the nose. The attacks last several hours and usually end in two days. Examination shows the nasal mucous membranes and turbinates pale, the air space is practically blocked and the conjunctiva shows similar changes. She can use Life Buoy, Vel and Softwash soaps without acquiring the sensitive symptoms. The soaps that give her the most trouble are Ivory bar soap, Ivory soap flakes, Chipso granules, Chipso flakes, Kirk's Flake White Bar Soap, Rinso granules, Lux, Bubble bath and, most of all, Dreft. Is there any agent present in the soaps which causes the symptoms? Could she be desensitized to the soaps which now irritate her?

T. P. Walsh, M.D., Garrett, Ind.

ANSWER—It is possible that soap is not the primary cause of the nasal symptoms but that it is a secondary factor which acts as an irritant in a nose sensitive specifically to other substances. The reason for suspecting this is that there is no pattern in the history as given to suspect sensitivity to any common ingredient of soaps. The composition of the various soaps mentioned not only varies from soap to soap but may vary materially in different batches of the same brand.

In general, soap is a sodium or potassium salt of any of the higher fatty acids. The fats used vary greatly from time to time depending on their market price and availability. Some of the common fats used are cottonseed oil, coconut oil, corn oil, linseed oil, kapok oil, rapeseed oil, olive oil, palm oil and sunflower oil. In addition, many animal fats are used, a few of which are prime tallow, bone grease, packing house grease and garbage grease. To these oils are added one or more of the following simple chemicals: sodium silicate, sodium metasilicate, trisodium phosphate, disodium phosphate, anhydrous tetrasodium pyrophosphate, sodium hydroxide, potassium hydroxide and sodium carbonate. These are the chemical constituents that go into most soaps.

In addition, various soaps contain perfumes or scenting substances, as creosote, contained in "Life Buoy." It is these scenting agents which are usually the cause of allergy. This does not appear to be the case from this patient's history. She seems to be as sensitive to the unscented soaps as to "Bubble Bath," which is highly scented. On the other hand, she tolerates "Life Buoy," which not infrequently is a cause of symptoms because of its creosote content, and is affected most severely by "Dreft," which is not a soap in the ordinary use of the term but consists of sodium lauryl sulfate and sodium sulfate.

We must conclude, therefore, that there are too many incompatible statements in this history to consider the likelihood of a single component in these various soaps as a cause of the symptoms. The most practical way of dealing with this type of case is to avoid soaps that the patient thinks are the cause of trouble and use only those that are not suspected. There is no successful way of desensitizing to soaps.

TOXICITY OF LUCITONE AND VERNONITE

To the Editor—A patient who is a dental technician works with Lucitone (methyl methacrylate resin, Du Pont) and Vernomite (acrylic resin Monal, Rohm & Haas Company, Philadelphia). These are inflammable compounds and volatile. I understand that cases of dermatitis have occurred with their use, and the manufacturers advise avoiding inhaling an excessive amount. Do you have any information concerning the toxic properties of these chemicals?

A. R. Twiss, M.D., Oakland, Calif.

ANSWER—More is known about Lucitone, the methyl methacrylate, than the Vernomite modification, although both are believed to be esters of acrylic acid. Using Rohm and Haas's methacrylate products, Deichmann (Toxicity of Methyl, Ethyl and *n*-Butyl Methacrylate, *J. Indust. Hyg. & Toxicol.* 23:343 [Sept. 1941]) has presented well defined experimental data on a series of these compounds. Through oral administrations, cutaneous applications, subcutaneous injections and vapor inhalation these materials were tested leading to evidences of pathologic effects. The low volatility of some methacrylates are unfavorable to the duplication of some results under actual industrial conditions. High concentrations led to accelerated

respirations, motor weakness, dyspnea, diminished reflexes, increased defecation and urination. In such animals as died, death occurred in coma as a result of respiratory failure. In case the introduction of these methacrylates was by the inhalation route, local irritation of the mucous membranes occurred, in addition to the aforementioned features. Cutaneous application produced local but temporary irritation, and the possibility is that cutaneous absorption may take place. The urine of certain animals showed hemoglobin. In some animals the blood porphyrin is high. The respiratory tract is, however, the site of the severest pathologic changes. From oral administration, corrosion of the wall of the stomach followed. Nineteen mg. of methyl methacrylate per liter of air killed all animals within five hours. Subcutaneous introduction, although leading to fatal poisoning, required larger quantities than in the case of oral administration. The inference is that methacrylates may be regarded as toxic agents at least under some circumstances. The possibility exists that the prolonged absorption of small quantities may lead to the production of porphyrins which through photo action may lead to dermatitis or other physiologic abnormalities. More extensive information may be found in Frederick, D. S. *Acrylic Resins, Modern Plastics* 16:16, 1938.

POSSIBLE URTICARIA FROM SOLVENT

To the Editor—A patient has a generalized urticaria involving almost the whole body surface except the face and hands. It began on the feet and spread over the rest of the body in about three hours. The patient is a dry cleaner and for the past two years has been working with Skellysol T (flash point 140 F.) as the dry cleaning solvent. To this is added powdered asbestos as an adsorptive agent. Once a week caustic soda is added to the system to recondition the solvent and clean the filters. Is there anything in this process that could be the cause of the urticaria? It came on about twenty-four hours after the caustic soda wash was used. Have any reports on the toxicity of Skellysol T been made to date?

John B. Dressler, M.D., Ida Grove, Iowa

ANSWER—This type of solvent is preponderantly a petroleum derivative on the order of naphtha. Such materials are known to produce dermatitis, "naphtha jags" and rarely chronic systemic naphtha poisoning. Generalized urticaria is unusual but possible. The beginning point of the urticaria on the feet rather than some exposed portion of the body does not suggest a result from direct contact. The work of any dry cleaner is likely to provide exposures to a wide variety of pollens and other dusts on garments prior to cleaning. If there is any connection between work exposure and the urticaria, the last mentioned factor may be of greater significance than the solvent materials. However, to rule out the latter, contact tests should be made with the several ingredients mentioned, as well as the mixture as a whole. Since the straight naphtha and the sodium hydroxide obviously will produce direct irritation, any test made should utilize high dilutions, such as with acetone in the case of naphtha and the mixture, while for sodium hydroxide aqueous dilutions may be made. The absence of reaction to any of these substances should lead to investigation of other causes.

LADDER WIRE SPLINTS

To the Editor—Can you give me a description of the "ladder wire splints" used by the Army? F. L. R. Roberts, M.D., Spirit Lake, Iowa

ANSWER—The term ladder wire splints used in the Army refers to the so called Cramer wire material used as a splint. It is described in a government pamphlet (Medical Field Manual Splints, Appliances and Bandages, prepared under the direction of the Surgeon General, Field Manual 8-50, United States War Department, 1940). The frame is made in the form of three sides of a rectangle $3\frac{1}{2}$ by 31 inches, with one short side missing, made of number 9 B and S gage malleable iron wire. The crosspieces are made of one continuous piece of number 15 B and S gage malleable iron wire shaped in the form of a gridiron with parallel bars about $\frac{1}{8}$ inch apart. The gridiron section of wire is attached to the frame by tightly wrapping with a malleable iron wire of about number 22 B and S gage, three turns to each lateral section and two in between being made. Ends are well wrapped and secured. After assembly the splint is heavily galvanized.

It is used (1) in splinting for transportation of Pott's fractures, injuries, and fractures about the ankle and foot, in peace time gauze and cotton pads and in war a large first aid packet being used as padding, the splints, when padded and applied, are held in position by a bias muslin bandage (2) as a transportation splint in the field or in the hospital, or (3) when a malleable light splint is required for a temporary period for the shoulder, elbow or wrist to maintain a fixed position other than that of extension.

SURGICAL CORRECTION OF CONGENITAL
MALFORMATIONS

To the Editor:—1. A child now 2 months old was born with extensive malformations. There are bilateral complete cleft palate and harelip, bilateral club foot, webbing of the fingers of the left hand and absence of one of the joints of the ring finger of the right hand. Despite these severe handicaps the child has grown and is now a strong, lusty baby. Could you give the generally accepted opinion as to the best time for surgical correction of the abnormalities? J. Stuart Staley, M.D., Morion, Va.

To the Editor:—2. A patient 5 months old has webbing of the second and third fingers on each hand. One hand, the left, permits of free movement and pulling of the connecting skin, the anterior and posterior layers of the skin presenting no interposing tissue. On the right hand the interconnection is much less movable and presents a thicker layer between the two dermal layers; the fingers are inseparable by manipulation, although there seems to be no intimate connection between the deeper structures of the fingers themselves. Would you advise, generally, to operate now or to wait until the child is older? If the latter, at approximately what age would the functional result be most promising? Where can I find literature which goes into the subject in detail?

William H. Mohsperger, M.D., Buffalo.

ANSWER.—1. The repair on the lip should be started within the first six weeks if the child is in good condition; otherwise, as soon as the general condition can be built up. The club feet can be manipulated and put in plaster at the same time. The repair of the palate should be postponed until the child is at least 18 months old. Unless there is complete fusion of the fingers including the terminal phalanges it has been found advisable to delay operative work until the child is about 6 years old. If the terminal phalanges of fingers, of unequal length, are fused, they should be separated past the distal joint as early as the first year in order to allow individual growth. The complete operation should be done at about the age of 6 years.

2. Experience has shown that it is advisable to delay operative work in cases of congenital syndactylism until the patient is about 6 years old. However, should two fingers of unequal length be completely fused, including the terminal phalanges, then they should be separated past the distal joint when the child is about 1 year old in order to allow free growth of both fingers.

Davis, John Staige, and German, William J.: Syndactylism (Coherence of the Fingers or Toes), *Arch. Surg.* 21: 32-75 (July) 1930.

POSTOPERATIVE SHOCK OR "LIVER DEATH"

To the Editor:—A well developed man aged 54 and slightly overweight had a gastric resection. It was necessary to give the following anesthetics to get adequate relaxation: (1) pentothal sodium 1.5 Gm., (2) ethylene and ether vapor and (3) ether given by the drop method. The operation lasted three hours. After the operation the patient complained of extreme pain and had considerable oozing of blood into the stomach. He showed signs of circulatory collapse, the temperature rising the second postoperative day to 107 F. and the pulse rate increasing from 64 to 104. This history is brief, but I wonder if it fits in with "liver death"?

Mary J. Erickson, M.D., Thomasville, Ga.

ANSWER.—The description of the patient's postoperative course would lead one to suspect that the cause of death was shock associated with secondary hemorrhage. This probably was due to a prolonged, difficult operation.

The etiologic factors concerned in so-called liver death are poorly defined. For the most part, in reported cases liver death has followed operation on the biliary tract, usually cholecystectomy, and there has been some evidence that it is due to disturbances of the blood supply to the liver. The same result can follow thrombosis of the portal vein. If the portal vein or the hepatic artery was disturbed during the course of the gastric resection, the resulting disturbance to the liver and to hepatic function added to the shock of the surgical procedure might have been a factor in the rise in temperature to 107 F.

DERMATITIS DUE TO SHAVING

To the Editor:—What is the prophylaxis and treatment of the dermatitis following shaving, especially in the neck? Is there some specific way of preventing the shaved hairs from growing into the epidermis and causing a rash? What shaving apparatus would you advise?

M.D., Canada.

ANSWER.—The proper prophylaxis of the dermatitis that frequently occurs after shaving is to avoid close shaving and to use an antiseptic lotion or a suitable cream. To prevent the shaved hairs from growing into the epidermis, the patient should be advised to shave along the line of growth of the hair of the beard instead of against it. The use of one of the standard electric razors may prevent the occurrence of this condition.

SNELLEN'S TEST FOR VISION

To the Editor:—For the calculation of loss of central visual acuity I have been using for near vision the A. M. A. reading card (Snellen's test type for near vision). Same company physicians use the Jaeger method of testing for near vision. To facilitate computation, please let me know the equivalent of each Jaeger type in terms of Snellen's test type for near vision.

Jose S. Santillon, M.D., Manila, P.I.

ANSWER.—The Jaeger series for testing near vision was never standardized, and various editions show considerable divergence in the size, shape and character of fonts used. It is impossible to present reading matter in lower case that precisely conforms to the mathematical requirements of optics. The reduced optotype is the only scientifically accurate means by which the acuity of near vision can be ascertain. Consequently short words composed of optotype block letters are used in the A. M. A. reading card for rating visual efficiency at the near point (14 inches, or 35 cm.). The Jaeger numbers roughly correspond to the following:

Jaeger Number	Point Type	A. M. A. Card (14/—)	Distance Equivalent	Percentage Visual Efficiency
1	3	14	1.0; 20/20	100.0
2	4	17	0.8; 20/25	95.0
3	5-6	23-28	0.6-0.5; 20/30-20/40	91.4-83.6
4	7	31	0.44; 20/45	79.3
5	7½	33	0.42; 20/47	78.0
6	8	35	0.4; 20/50	76.5
7	9-10	47-50	0.3-0.28; 20/65-20/70	66.6-67.8
8	11-12	52-56	0.27-0.25; 20/71-20/80	62.2-58.5
10	13	61	0.23; 20/87	54.9
12	14-16	67-70	0.22-0.20; 20/90-20/100	53.4-48.0

MASSAGE AND OSTEOARTHRITIS

To the Editor:—A patient says that she was told at an out of town clinic that she should not permit any one to massage her knees for hypertrophic arthritis. Is this an accepted idea, and if so why? I ordered gentle massage after diathermy.

M.D., Clinton, Iowa.

ANSWER.—Diathermy followed by gentle massage is a common form of treatment for osteoarthritis (hypertrophic arthritis) of the knee. It is a principle in the application of massage in the treatment of arthritis that it should never add by trauma to the inflammatory or otherwise diseased process already present. It follows from this that massage for the most part should be given in the neighborhood of but not immediately over the site of the arthritis. There are some exceptions to this statement in that gentle stroking massage may sometimes be profitably applied over a diseased joint.

DERMATITIS FROM EYEBROW PENCIL OR NAIL POLISH

To the Editor:—A patient aged 48 has a eczema about the eyelids and the forehead which I believe is due to the use of an eyebrow pencil. She is otherwise in good health. Physical examination and all laboratory examinations give normal results. Do you know what is in eyebrow pencils which might cause eczema? Do you know of any such material that will not cause an allergic reaction?

M.D., Minnesota.

ANSWER.—The composition of the average eyebrow pencil is lamp black, paraffin, liquid petrolatum or petrolatum. This is a simple and for the most part harmless cosmetic. In all probability the eczema about the eyelids and the forehead is due to nail polish. Many cases of this sort have been reported in the literature in the past few months. This source of irritation should be investigated.

USE OF ESTROGENS FOR DIABETIC PATIENTS

To the Editor:—Would you kindly give me some information regarding the use of estrogenic hormones in the amenorrheas of the diabetic patient and what the effect is on the course of the diabetes.

Edna F. Patterson, M.D., Tokomo Park, Md.

ANSWER.—Estrogen, thyroid or combined estrogen and progesterone therapy may be used for the diabetic as for the non-diabetic and will have neither a beneficial nor a harmful effect on the course of the diabetes.

QUEEN ELIZABETH'S CONTRIBUTION TO MEDICINE

To the Editor:—The Examining Board for Nursing Registration in this state recently included among its examination questions, "What did Queen Elizabeth do for medicine?" I am unable to find any answer to this question. Can you supply the information?

R. A. Kilduffe, M.D., Atlantic City, N. J.

ANSWER.—In 1565 Queen Elizabeth issued a statute permitting the dissection of executed criminals.

ACUTE ABSCESS OF THE THROAT IN CHILDHOOD

WILLIAM DEERING, M.D.

CHICAGO
AND

JOSEPH BRENNEMANN, M.D.
LOS ANGELES

This report deals with 250 cases of true and potential, or abortive, abscesses in the throats of children under 14 years of age observed in the wards of the Children's Memorial Hospital, Chicago, over a period of ten years ended Dec. 31, 1940. In 181 of these cases there was frank suppuration, as shown by spontaneous rupture or surgical drainage. In the remaining 69 a localized inflammatory lesion, apparently differing in no way from the lesions in the early stages of the other group, subsided without evident pus formation for one reason or another. Nearly all of these cases were treated in the pediatric service exclusively except when laryngologic help seemed indicated as in any analogous situation. This rather unusual procedure requires some justification, at least an explanation.

At the Children's Memorial Hospital, except for one resident in pathology, all the house staff are future pediatricians or general practitioners and all of these rotate through the special as well as the pediatric services. In other words, there was no resident in laryngology to train for the practice of his specialty. Since the pediatrician and the general practitioner are obviously in the only strategic position to see the early stages of abscess formation, it is logically important that they should have adequate training in that direction. They have, moreover, from the nature of their experience a wider knowledge of clinical setting in general and of specific differentiation from other conditions with which an abscess might be confused than has the laryngologist who comes into the picture at, or near, the finish. To the experienced pediatrician this becomes evident as he scans the reports in the literature on this subject, nearly all of which come from laryngologists.

The pediatrician is a general practitioner who limits his practice to a certain age group, and it naturally follows that it may be difficult in a borderline situation to determine, to the satisfaction of all concerned, whether a given relatively minor case is logically and safely pediatric or, indeed, safely surgical. We feel that the simple abscess which constitutes the vast majority can safely be left in pediatric hands, while the more serious lesion, or complication, calls for the help of the laryngologist. Furthermore, except in case of hemorrhage from erosion of a prominent artery or of invasion of the mediastinum, both rare in childhood, or of those even rarer cases reported in the literature, which we

have never encountered, in which a mere examination leads to sudden death, a fatality is nearly always due, not to the abscess itself, but to pulmonary, septic and other conditions in which the pediatrician is on more familiar ground than is the laryngologist. In all serious cases team work, at least, is indicated. The local lesion always has a child attached to it, and the child is often far more important than the local lesion. Finally, when Richards¹ in his authoritative paper on retropharyngeal abscess, after emphasizing the importance of a correct diagnosis and pointing out that 29 of his 162 cases were diagnosed incorrectly, comments "Mention of these errors is not in any way intended to cast aspersions on . . . en of the examining physician, but simply to call attention to the various deceptive signs and symptoms which this one single condition can present," one would seem justified, in the same kindly spirit, in considering this as further evidence of the need for more adequate training along these lines of the future pediatrician and general practitioner, who will eventually be called on, in nearly every instance, to stand in the first line of defense against such error in diagnosis. This view finds further confirmation in the following quotation from the same source: "Greenwald and Messaloff state that in their experience retropharyngeal abscess escapes recognition more frequently than any other acute disease in childhood. None of their cases came to them with this diagnosis but had been treated for from one to three weeks with no suspicion of the correct diagnosis. It is only fair, however, to state that the majority of these cases had not been seen by a laryngologist, who naturally would be more likely to detect the presence of an abscess." Because of the emphasis which we have always placed on the recognition of these abscesses, the errors in diagnosis on the part of our pediatric resident and outpatient staff were practically negligible.

Our purpose, then, is to present our observations from a pediatric point of view, in a simple clinical way, without anatomic or pathogenic detail, in the hope that they may be of interest and service to the pediatrician and general practitioner, and possibly to the laryngologist because of the method of approach.

From a purely clinical point of view we recognize three main types of acute abscess of the throat in childhood: retropharyngeal, retrotonsillar and peritonsillar, or quinsy. Parapharyngeal abscess will be considered as a complication, an extension, of one of these abscesses into the parapharyngeal space, or pharyngomaxillary fossa. Retropharyngeal abscess due to caries of the cervical spine does not belong in a discussion of acute abscess of the throat. No such abscess, moreover, occurred during the period covered by this series. While the differentiation between the different types of abscess

1. Richards, Lyman: Retropharyngeal Abscess, *New England J. Med.* 215:1120-1130 (Dec. 10) 1936.

is usually easily made, we have not always found it to be so especially in infancy. We have been compelled to record 8 as "uncertain" and we are not sure that our interpretation of the others is correct in every instance. We do feel sure that it is sufficiently accurate to make our statistical summaries as informative as if a few possible misinterpretations had not occurred. Because of our special interest in the subject, in the case of one of us extending over several decades, our own diagnostic and progress notes, as well as those of the house staff and the attending pediatricians and laryngologists, were more than usually full and adequate for our present purpose.

We have been impressed by the fairly constant chronological setting of the different types of abscess. Thus, the retropharyngeal abscess was almost restricted to the first two years of life; the retrotonsillar abscess came into prominence in the third and fourth years and tapered off after the seventh or eighth year; one peritonsillar abscess occurred in a child of 5 years, the rest from the seventh year on.

All of these acute abscesses have four cardinal signs or symptoms that vary in degree but are rarely absent:

1. An infection in the throat, preceding or concurrent.
2. Pain on swallowing. Children rarely complain much with an uncomplicated throat infection. If pain on swallowing, even to some extent without swallowing, supervenes on such an infection an abscess must be suspected. The pain is usually distressing, varying in degree with different types of abscess and naturally leads to a disinclination, even a refusal, to eat. It is promptly relieved if the abscess breaks or is drained surgically.
3. Localized swelling in the throat, the site depending on the type of abscess. This may or may not be visible; it can always be made out by palpation.
4. Unilateral, or predominantly unilateral, cervical adenitis on the affected side. Throat infections are commonly accompanied by pain, tenderness and swelling of the corresponding cervical lymph nodes, often to a pronounced degree. The adenitis tends, however, to be about equal on the two sides. A definite unilateral predominance, usually quite obvious to the eye, should always lead to suspicion of an abscess in the throat on the same side. Bilateral involvement of the cervical glands should occur with simultaneous bilateral abscesses in the throat, but this practically never occurs in childhood.

Other signs and symptoms of warning significance, such as noisy breathing with snoring and choking sounds; nasal, or mushy sound of the voice and cry; laryngeal obstruction with dyspnea, stertorous breathing and some cyanosis; regurgitation of fluids through the mouth and nose on swallowing; prominence of one tonsil or one side of the throat; deviation of the uvula away from an affected side, may occur to a varying extent with one or the other type of abscess. Their occurrence in the different types will be discussed under the appropriate headings. No significant relationship could be made out between the degree of fever and the severity of the illness, and no helpful prognostic information was obtained from blood counts. The fever ranged from near normal to 106 F. and the leukocyte count from normal to 82,000. In general both fever and leukocyte count ranged higher in the children with retropharyngeal abscess than in the others.

RETROPHARYNGEAL ABSCESS

A retropharyngeal abscess is a suppurative involvement, secondary to an infection in the throat, of one or more of three to five paired lymph glands that lie parallel to one another on each side of the posterior pharyngeal wall in the potential space between the pre-

vertebral fascia and the posterior pharyngeal mucosa. These are said to atrophy after the third or fourth year, although "one or two remain on each side" (Lederle). It is generally assumed that this accounts for the fact that this kind of abscess is so rare after the period of infancy. If an upper gland is involved, or if there is an extensive abscess, this can usually be seen in the posterolateral angle of the pharynx. If the lower glands are involved they cannot usually be seen with ordinary pediatric technic; the palpating finger can, however, easily locate the swelling and can at the same time determine if fluctuation has occurred, and if so, to what extent. With such a low abscess there is now, in addition to the four cardinal symptoms, noisy, snoring, choking respiration, sometimes together with dyspnea and stertorous breathing as the larynx is impinged on. Cyanosis may occur but is rarely serious. The voice and cry are nasal and muffled in quality. Regurgitation through both nose and mouth may occur if the baby bravely attempts through hunger and thirst to overcome the handicap of painful swallowing. The tonsil is not pushed forward and there is no gross distortion of the throat as in the other types of abscess.

As in lymphadenitis elsewhere, suppuration may or may not occur. We did not, of course, attempt to determine the presence or absence of such involvement unless there were definite retropharyngeal symptoms. Of 105 cases of known retropharyngeal adenitis in our series, 23 subsided without apparent suppuration either spontaneously or following the administration of sulfanilamide; in 82 there was frank suppuration. Only the latter will be used for statistical purposes, as also in the other types of abscess. There was, however, no significant difference in the incidence as to the age of the child in the suppurative and nonsuppurative cases. Nearly 90 per cent of our 82 cases of retropharyngeal abscess occurred in the first two years of life, nearly 98 per cent in the first three years. Three of the infants were only 3 months old; one child was 3 years old and another 5 years of age.

RETROTONSILLAR ABSCESS

By retrotonsillar abscess we mean an abscess directly behind the tonsil in the lateral pharyngeal wall. In the literature this is sometimes included under "peritonsillar" abscess. The swelling may or may not be visible on simple oral examination, but it is readily made out by palpation. The latter too is the surest method of determining whether suppuration has occurred and to what degree. In addition to the four cardinal symptoms and signs there is another that is equally constant: the affected side of the throat is not only more prominent, an asymmetry that is nearly always significant; the tonsil is pushed forward and mesially so that more of it is visible than of its mate. This is in striking contrast to quinsy, in which the swelling is mesial to and in front of the tonsil, so that the latter is pushed back and out of sight or nearly so. Children with retrotonsillar abscess are usually not as sick as are the infants with retropharyngeal abscess and much less so than older children with quinsy.

It has seemed to us that this type of abscess deserves more attention than has been given to it. In our series there were 79 cases with suppuration and 38 in which there was prominent localized swelling which subsided without drainage, either spontaneously or following treatment with sulfanilamide. There were thus only a few less than of the retropharyngeal type. We feel confident, however, that our interpretations were correct

except possibly in a few instances in late infancy. Only 2 occurred before the end of the second year of life. They were most numerous in the third and fourth years, about one half of the total number occurring during this period. After this they were fairly equally distributed up to and including the eighth year, after which they rapidly dropped to 4 in the ninth year, 3 in the tenth and 1 each in the eleventh and twelfth.

PERITONSILLAR ABSCESS

There were 11 cases of peritonsillar abscess, or quinsy, and 8 cases in which an initial swelling subsided either spontaneously or following the use of sulfanilamide. The youngest child with an abscess was 5 years old; the others were 7, 8, 9, 10 and 11 years of age, each year represented by two abscesses. This adds further support to the well known fact that quinsy is a rarity before the sixth or seventh year and that the incidence is low all during childhood as compared with that of other abscesses or with later life. In addition to the symptoms and signs common to all abscesses there is the obvious swelling, or bulging, mesial to and in front of the tonsil, causing the latter to recede and the uvula to deviate to the opposite side. A striking and characteristic sign, absent in all other kinds of abscesses of the throat, is the inability to open the mouth to more than a very limited extent, owing both to trismus from local conditions in the throat and to extreme pain when it is attempted. The rather prolonged course of the disease, the constant pain, the extreme dysphagia, the high fever, the loss of sleep, all lead to a severe degree of prostration and loss in weight.

PARAPHARYNGEAL ABSCESS

Only one parapharyngeal abscess was encountered. This will be discussed later.

EFFECT OF TONSILLECTOMY

In only 11 instances were abscesses found in children on whom a tonsil and adenoid operation had been done. Seven of these were retrotonsillar, 2 were peritonsillar and 2 were "uncertain."

DIAGNOSIS

The diagnosis of an abscess in the throat should rarely be missed if the condition is constantly in mind in the presence of any of the signs and symptoms that are so characteristic. Differentiation between the various types of abscess is sometimes difficult, especially in infancy and early childhood or if spontaneous rupture has occurred. In the great majority of cases it is not. In this series we were "uncertain" eight times for one reason or another. In addition to what has been said, two things may well be stressed: the diagnostic importance of palpation and the ominous warning significance of hemorrhage.

While certain abscesses can be seen, the palpating finger is always more revealing as to the location and, even more important, as to the stage of development. It is a simple procedure. It requires however a special technic, of which speed is an important factor. We have fortunately had none of those experiences which have been recorded, such as alarming symptoms, apnea and even death from the mere insertion of the finger or a tongue blade, although repeated examinations are usually indicated in order to note progress, and many more are made in a hospital for pedagogic reasons. Except for the toothless baby, some form of mouth gag is indicated if the finger is bare, and the pediatrician can feel more with a bare finger than with one that is

covered by a rubber glove. A convenient and efficient mouth gag consists of two medium width tongue blades inserted on edge between the upper and lower maxillas in the region of the molars. This is more easily and readily removable and to us seems safer than the commonly used more cumbersome mouth gag. In examining for retropharyngeal abscess the moistened finger is rapidly passed over the tongue and down the pharynx. This method is probably the safer one but has the disadvantage of having the ungual surface of the finger next to the abscess. In larger infants the finger can safely be passed from above if too great force is avoided. This brings the palpating surface more naturally against the site of the abscess in the posterolateral angle of the pharynx. The examination must be made quickly without force, and care must be taken, if the finger is bare, that it is withdrawn before the tongue blades are removed. A bite in the presence of an infection in the throat is not without danger, as one of us can testify from personal experience. If there is a severe adenitis or an abscess, the normally concave posterolateral angle of the pharynx is obliterated on the affected side by a rounded protruding swelling. If fluctuation is present, it can readily be made out and also the degree to which it has advanced.

In palpating a retrotonsillar or a peritonsillar abscess, much the same technic is applied except that the finger is best inserted at the angle of the mouth on the affected side.

Frank bleeding supervening on an abscess in the throat must always lead to the suspicion of a parapharyngeal abscess with erosion of a large blood vessel, usually the common or internal carotid, although the vertebral artery may be the source of the hemorrhage, as in a case reported by Richards. Repeated pharyngeal hemorrhage practically establishes the diagnosis and makes the indication for surgical intervention imperative. There was only 1 case in our series, that of a boy of 7 years who died of a sudden massive hemorrhage.

PROGNOSIS

The outlook in throat abscesses in children is generally favorable, although there is a potential danger that must always be kept in mind. Death is rarely due to the abscess itself; more often it follows from an infection of which the abscess is a complication, not a cause. This is confirmed in our series. There were three deaths. Only one of these, the parapharyngeal abscess, was unquestionably due to the abscess itself. The other two followed retropharyngeal abscesses. One occurred in an infant of 7 months with "a low abscess encroaching on the larynx." The abscess was opened by one of the laryngologists, who reported obtaining about 2 drachms (8 cc.) of pus. Five days later he noted "Pharyngeal swelling practically all gone. Breathes normally." Two days later there was definite pneumonia, followed by a severe diarrhea, to which the infant succumbed twelve days after the abscess was opened. The necropsy report stated "Mucosa of pharynx intact. Small area of infection at site of abscess drainage. Mediastinum normal." This baby, moreover, had an eczema, a well known risk in any respiratory infection.

The second death following a retropharyngeal abscess was in an infant of 11 months with an extensive bronchopneumonia and an admission temperature of 106 F. There was so much obstruction to breathing that a tracheotomy was considered. There was "moderate

opisthotonos and a spinal fluid cell count of 66." A small abscess was opened by the laryngologic service. Two days later the following notation was made: "Retropharyngeal swelling has disappeared. Breathing is much easier." The temperature remained around 105 F. and the child was kept in an oxygen tent. Death occurred on the following day, obviously from an overshadowing bronchopneumonia. Although death could hardly be attributed to the abscess itself in either of these 2 infants they will be included in a statistical summary, as is usually done, because they died after a retropharyngeal abscess.

The total mortality of all patients with abscesses was 1.7 per cent; of those with retropharyngeal abscesses, 2.4 per cent. Statistics of mortality from any one source may be seriously misleading. The element of luck may easily play a major part. Thus, Richards reports a mortality of 7.4 per cent in 162 cases of retropharyngeal abscess. Luck was not with him, since of his twelve deaths two were due to hemorrhage, one from a carotid and one from a vertebral artery; one to an insertion of a tongue blade; one to a preliminary laryngoscopy, one to a mediastinitis; one occurred three hours after a spontaneous rupture and in four there was a generalized septicemia. He¹ reports the mortality following retropharyngeal abscess in the hands of others as follows: Frank in 1921, 6.7 per cent in a series of 74 cases; Babbitt in 1924, 10 per cent in 50 cases; Guthrie in 1926, 15 per cent in 20 cases; Greenwald and Messeloff in 1929, 7.3 per cent in 55 cases; Bokai 4.4 per cent in 317 cases; Wishart in a series of 41 cases had only one death and that in a moribund patient, a preoperative fatality. From all this it is evident that an abscess in the throat of a child must not be taken lightly and also that luck seems to have been with us in our series.

TREATMENT

The general treatment is much the same as that of any serious infection of the upper respiratory tract and need not concern us in this connection.

We feel very strongly that in the local treatment of any abscess of the throat, other things being equal, we should wait before establishing drainage until there is not only fluctuation but advanced fluctuation, or pointing. Healing occurs more promptly and more surely if the abscess has fully matured; there is probably less danger of systemic invasion, and the necessity of repeating the operation is reduced to a minimum. This attitude explains, at least in part, the high incidence of spontaneous rupture, which, even to us, is a bit surprising in retrospect. Except in the case of the child with a parapharyngeal abscess there was, however, no serious complication following spontaneous rupture, and in this instance the abscess had broken long before the child came under our observation. Frankly, however, we were often a little chagrined, but not worried, when this occurred, as we naturally believe that an abscess should be opened when it is ripe both for the child's sake and for the training it affords. This does not apply to retrotonsillar abscess as fully as it does to the other types, as will appear later. Of eighty-two retropharyngeal abscesses thirty, of seventy-eight retrotonsillar abscesses sixty, and of eleven peritonsillar abscesses six drained spontaneously.

When abscesses were opened surgically this was done routinely by the assistant resident in the service at the time. The forceps was used in every instance except in a few cases treated by the laryngologists with the

scalpel. In the case of three retropharyngeal and one retrotonsillar abscesses, either for class demonstration or because of an ominous outlook, one of us (J. B.) assumed the responsibility. Five retropharyngeal and five retrotonsillar abscesses were opened by the laryngologists, in three instances with forceps and in seven with a scalpel. The five peritonsillar abscesses that were drained surgically were all done by the laryngologists with a knife. Anesthesia was not employed for several reasons: because it constitutes a hazard from local conditions in the throat, because there is commonly a concurrent respiratory tract infection, because of the danger of aspirating pus while the cough reflex is abolished or obtunded and, finally, because of the effect on the child of an anesthesia as compared with that of the momentary, relatively slight pain that goes with opening a ripe abscess through a thin walled, pathologic mucosa.

The retropharyngeal abscesses were treated with the child in the erect position. Snugly wrapped in a sheet he was seated with the legs free on the lap of one assistant, while another held the head and inserted two medium width tongue blades on edge, as a gag, between the upper and lower maxillas. Even more here than in the mere digital examinations we feel that there is less danger from the use of tongue blades than from the usually employed, more cumbersome, mouth gag, because they are so much more quickly removable, especially in an emergency. Facing the child, the operator inserts a moistened index finger over the root of the tongue, locates the point of maximum fluctuation and with the finger still in the throat quickly inserts a fairly sharp pointed forceps into the abscess and opens it slightly. The baby is immediately tipped forward and held in a horizontal position for a time so as to avoid aspiration of the first gush of pus. He is then kept in bed on his stomach or on one side for some hours. In only a few instances was it necessary to repeat the procedure, usually because it was done too early or the opening was too small. The subsequent course can readily be evaluated by the degree of relief of all symptoms and if necessary by digital exploration.

The whole procedure, from the time the tongue blades are inserted to the time when the infant is tipped forward need not, and should not, take more than five seconds, certainly not more than ten. This in itself has an appeal as compared with the more time consuming exaggerated prone, or Rose, position, apparently increasingly advocated by laryngologists. In this position, with the head extended backward the abscess is opened under direct vision with a knife, often followed by a forceps to widen the opening and by suction to minimize the danger of aspiration of pus. The pediatrician at least can see better with the end of his finger than he can with a laryngoscope and he doesn't trust himself with a knife in the throat of a struggling baby. There is, of course, no evidence available that either method carries a lesser mortality or morbidity than does the other. We feel too that if the child had a choice he would much prefer to face the ordeal in the erect rather than in the unnaturally constrained prone position, and, after all, the effect on the mind even of an infant must be weighed in the balance. The first gush of pus when the abscess is opened in the erect position adequately empties the cavity, and any danger of aspirating pus later has seemed negligible and would, after all, be about the same in the two methods of procedure. We are also inclined to think that the ragged

opening made with the forceps is less apt to close prematurely than is the cleancut opening made by a knife, thus calling for less frequent need for reoperation.

Approximately 76 per cent of the retrotonsillar abscesses ruptured spontaneously. This was not accidental; we allowed most of them to do so. They come to a head rather rapidly as a rule, have a thin walled covering and commonly rupture within a few days. There is usually not a very large amount of pus, and the children are only exceptionally as sick or in as much discomfort as are those with the other types of abscess. In older children, and nearly all of the retrotonsillar abscesses occurred well beyond the second year of life, there is a certain amount of psychic trauma that can be avoided if the abscess is allowed to follow its own course. We have had no occasion to regret pursuing this method of procedure. Only when things did not progress favorably, when the course was unduly prolonged or there was marked dysphagia or discomfort did we intervene surgically, nearly always with the forceps and in much the same manner as detailed under the treatment of retropharyngeal abscess.

To what extent nature will sometimes take care of things along devious routes was illustrated in the case of a child of 5½ years with an abscess back of the left tonsil. Mere pressure on the ripe abscess by an examining finger caused a copious discharge of pus to shoot for some distance from the left ear. On cleaning the ear canal and again making pressure on the abscess, one could see pus welling through an opening in the anterosuperior wall of the external auditory canal. Recovery followed without further treatment. There was no discharge into the throat at any time. This may have been poor surgery, but it does convey a lesson.

The course of a retrotonsillar abscess, both advancing and receding, can readily be followed by noting the degree of subjective symptoms, by the position of the tonsil and if necessary by palpation. Relief is often spectacular. An older child who can hardly be induced to swallow any supper will often eat a hearty breakfast if the abscess has broken over night.

True peritonsillar abscess, or quinsy, we were glad to turn over to the laryngologists, always with the hope that they would not operate too early or that it would rupture spontaneously. The old saying that if no pus was obtained there was "a relief from congestion" has, fortunately, pretty much gone into the limbo of discarded therapeutic attitudes. The characteristic inability of the child to open his mouth to a pediatrically workable degree and the uncertainty of hitting the abscess and nothing else, call for the special skill of the laryngologist. While it is desirable, per se, to await obvious pointing of the abscess, the distress and prostration are so great that intervention is often indicated as soon as definite fluctuation, or the spot at which pointing will occur, can be made out. That many of them, under favorable circumstances, will rupture spontaneously and safely is shown by the fact that more than half of those in this series did do so, i. e. 6 of 11 cases.

The course and treatment of the one parapharyngeal abscess that occurred in our series point, once again, to the fact that the rare lesion, as this is in childhood, is apt to be misinterpreted, or temporized with, especially when the only relief can come from a mutilating operation with potentially serious sequelae. The ominous, warning significance of a hemorrhage from

an abscess of the throat, especially if repeated, can well be emphasized again. This boy of 7 years had had a sore throat for two weeks, high fever, predominantly unilateral cervical adenitis, pronounced dysphagia, some spitting of blood for two days and a petechial eruption on his legs and torso obviously due to sepsis. When seen by one of us in the outpatient department, cautious inspection showed an intense redness and a swelling and edema that nearly obliterated all landmarks. There was some bleeding. A digital examination was unfortunately made by one of the house staff with a resulting fairly large and rather prolonged hemorrhage, which subsided after a time. There was an unfortunate delay in resorting to surgery, not due to the laryngologic service. Nine hours after admission he was taken to the operating room for ligation of the common carotid artery. The pharynx was now filled with fresh and clotted blood. With the beginning of anesthesia a sudden profuse hemorrhage occurred and death came promptly before ligation could be undertaken. In retrospect it is obvious that the procedure should have been instituted at once, although the result would probably have been the same in the presence of an advanced sepsis. At necropsy there was found "a large perforation of the posterolateral pharyngeal wall below the level of the tonsil" and "a large erosion of the internal carotid artery." The parapharyngeal space was "filled with a large clot that could be lifted out of the abscess cavity. Cultures from the abscess and from the blood stream yielded a hemolytic streptococcus."

SULFANILAMIDE

It was during the period covered by this series that sulfanilamide came into use. It was the only drug employed, because in the earlier years it was the only one of the sulfonamides current and also because we thought that a hemolytic streptococcus was probably the active agent. The drug was administered to 15 children with retropharyngeal, 10 with retrotonsillar and 3 with peritonsillar localized inflammatory lesions that seemed likely to go on to suppuration. Of these, 7 retropharyngeal, 5 retrotonsillar and 2 peritonsillar lesions did not suppurate. These figures give an incidence of subsidence without abscess formation approximately twice that of the whole series. No deductions are, of course, justifiable from so small a number and in a condition so variable and uncertain. It is, however, our general impression that an abscess may be forestalled if sulfanilamide, or one of the later drugs, is given early enough and in adequate dosage. The limitations of what constitutes "early enough" are obvious and remain to be determined from future experience. We feel that, in the light of our present knowledge, one of these drugs is clearly indicated if suppuration does not seem to have taken place.

The evidence that these drugs have only an inhibitory action and should not be given if suppuration has occurred is more convincing than the evidence that they should be given in the earlier stages. We have seen an abscess inhibited twice only to recur later when the drug was stopped, unhappily prolonging the illness and the discomfort. Eight infants with retropharyngeal abscesses were given sulfanilamide. Five of the abscesses ruptured spontaneously while the drug was being given, one was inhibited but developed a full blown abscess five weeks later, one was drained surgically eight days and another three days after the drug had been stopped. Of five retrotonsillar abscesses, four ruptured while the drug was being given and the fifth

came to a head three days after it had been discontinued. One peritonsillar abscess subsided temporarily with sulfanilamide but recurred six weeks later.

SUPPURATIVE CERVICAL ADENITIS

A final word as to the treatment of suppurative cervical adenitis that may result from any of these abscesses: In 12 instances, or 6.6 per cent, of our series, suppuration occurred. The incidence was inversely proportional to the age of the child, one half of them occurring before the fifteenth month. Cervical abscesses developed following seven retropharyngeal, four retrotonsillar and one peritonsillar abscess, the last in the youngest child in the series with that type of abscess. In addition to the factor of age there seems to be a direct relationship between the length of time that it takes for the abscess in the throat to come to a head and the likelihood of an eventual cervical abscess. We feel very strongly that these abscesses should not be opened until there is not mere fluctuation but definite advanced pointing with a thin walled glossy covering of the abscess cavity. A 5 mm. incision, if possible in a crease of skin for cosmetic purposes, together with drainage by means of a strip of rubber tissue or salvage edge of gauze for a couple of days is usually all that is necessary. If indicated, the incision can be kept open a few days longer by means of a groove director inserted just beyond the opening or by mere digital separation of the edges. The resulting scar is sometimes hard to find at a later time, a not unimportant item in an exposed area especially in the neck; and, again, the child is spared the greater pain of an early incision, the more prolonged drainage and the greater number of dressings.

There was 1 case in our series, the only one of its kind we have ever encountered, in which there was a direct communication between a cervical and a retropharyngeal abscess. This infant of 12 months entered the hospital with both a retropharyngeal and a cervical abscess, the latter, if anything, more advanced than the former, a very rare occurrence. When the abscess in the throat was opened the cervical abscess collapsed, and when pressure was made on the latter pus could be seen welling into the pharynx through the opening in the retropharyngeal abscess. Things seemed to progress favorably, but it was deemed more judicious to drain the cervical abscess externally five days later. Recovery was uneventful. In the older literature, especially, the advisability of opening some retropharyngeal abscesses externally nearly always comes up for discussion. It is hard to imagine any indication for external drainage of an acute abscess unless there is, as in this case, a free communication between the pharyngeal and the cervical abscess.

SUMMARY

In a clinical study of 250 cases of true and potential, or abortive, abscess in children under 14 years of age there were 181 abscesses and 69 cases in which suppuration did not occur. There were 82 retropharyngeal, 79 retrotonsillar, 11 peritonsillar, 1 parapharyngeal abscess and 8 of undetermined classification. There were two deaths following retropharyngeal and one due to parapharyngeal abscess. The total mortality was 1.7 per cent; that following retropharyngeal abscess alone was 2.4 per cent. Only one death was unquestionably due to an abscess itself, the parapharyngeal abscess. Complicating cervical abscess occurred in 6.6 per cent of the series.

THE INCIDENCE OF PELLAGRA IN OHIO HOSPITALS

WILLIAM BENNETT BEAN, M.D.

TOM DOUGLAS SPIES, M.D.

AND

MARION A. BLANKENHORN, M.D.

CINCINNATI

In the extensive medical literature there is no study which gives any comprehensive appraisal of the general incidence of pellagra. Such reports as are available come from public health reports, mortality statistics and figures for hospitalizations in areas where the condition has long been recognized as a menace to health. Furthermore, there is no indication of the prevalence of pellagra in regions of this country where it has not been studied intensively.

As a consequence, there seems to be a widespread impression that this type of deficiency syndrome is very rare in the Northern states and exists only as a provincial problem peculiar to the endemic areas of the South. Indeed, case reports indicate that it is considered an exotic disease except in subtropical climates. For a number of years we have been engaged in the intensive study of pellagra in both sections of the country and have collected data which dispel any uncertainty concerning the wide distribution of nutritional deficiency in representative cities in both sections of the country.

Two previous reports of pellagra in Ohio, while indicating the occurrence, gave no indication of its incidence.¹ A comparison of available figures drawn from published records of hospital admissions in several regions of the United States throws light on the frequency of pellagra in the so-called endemic and non-endemic areas. While such variables as standards for hospitalization and readmission, diagnostic alertness and availability of adequate interim treatment and dietary adjustment are not the same in different places, a study of pellagra admissions reveals some interesting facts about the problem of inadequate nutrition reflected by very ill persons requiring hospitalization and about pellagra occurring as a sequel of other diseases.

MATERIAL AND METHOD

This report deals with the initial admissions of patients with the diagnosis of pellagra in the Lakeside Hospital, Cleveland, and the General Hospital, Cincinnati, and a comparison with admissions to hospitals in other areas. The Lakeside Hospital is a private institution with extensive facilities for teaching and investigation. The Cincinnati General Hospital is a municipal hospital where all the services are arranged for teaching purposes. The patients were all seen by members of the house staff and attending physicians and, during most of the year, by the special group doing research in nutrition. We have restricted the study to first admissions because the interest in pellagra stimulated by the nutrition research workers may well produce an arti-

These studies were aided by grants from E. R. Squibb & Son and the Martha Leland Sherwin Memorial Fund.

Drs. V. P. Sydenstricker, J. M. Ruffin and D. T. Smith supplied figures for admissions used in the text and tables.

From the Department of Internal Medicine, University of Cincinnati College of Medicine and the Cincinnati General Hospital, Cincinnati, and the Department of Internal Medicine, Western Reserve University, and the University Hospitals, Cleveland.

ficial factor increasing admissions. This trend would be seen especially in subsequent entries which are excluded from the tabulations.

We have included only cases presenting pellagrous glossitis and bilateral dermatitis, because these diagnostic criteria have been used in the reports tabulated for comparison (table 3). Since we have emphasized the very early change in the mucous membranes of the mouth and tongue as a specific index of nicotinic acid deficiency, many patients are now seen and successfully treated at an early stage of deficiency before dermatitis has occurred. A few have been observed for a time without any specific antipellagric remedy, and these patients eventually developed typical dermal lesions. Even using these criteria we feel certain that we are still overlooking many persons with larval or subclinical pellagra and related vitamin deficiency disorders. Glossitis and dermatitis indicate severe deficiency, comparable at different places and periods of time.

On this basis we have selected the records of 113 cases observed in Cleveland from 1931 through 1935 and 128 cases from Cincinnati seen in the five years ended with 1939. Prior to the beginning of each period represented, there was no special study of pellagra in either hospital (tables 1 and 2). The Cleveland cases

Cases of pellagra.....	2	16	18	23	23	16
Percentage.....	0.2	1.4	1.4	2.4	2.3	1.5

constituted 1.5 per cent of all medical admissions, and the Cincinnati cases 0.95 per cent. The yearly increase in the number of cases diagnosed at each hospital probably reflects the interest stimulated by the intensive study of nutrition. The figures may well be interpreted as a result of dissemination of diagnostic skill rather than an increase in incidence.

RELATED STUDIES IN THE LITERATURE

Cases of pellagra are classified as endemic, alcoholic or secondary, depending on the chief cause of the vitamin deficiency. Among the endemic are included those in which food fads, idiosyncrasies, such as vegetarianism, and some ill devised therapeutic diets figure as well as those in which it has not been possible to obtain proper food. In alcoholic pellagra the vitamin wants have not been satisfied because the beverage alcohol, the chief source of calories, ordinarily contains none and the diet does not make up the deficit. The term secondary pellagra includes cases in which the diet, satisfactory for the ordinary requirements of health, is inadequate when some disease obstructs the intake, accelerates the loss or raises the needs for the vitamin rich foods. The resulting pellagra is intrinsically the same whatever the manner of its origin.

There are several reports of hospital figures on pellagra in various Southern states prior to 1930, but data are not available for comparison with total hospitalizations. Boggs and Padget,² in a study of pellagra in the Baltimore City Hospital from 1911 through 1930 inclusive, found 102 cases in 16,572 admissions, an inci-

dence of 0.68 per cent. There were a few more in the alcoholic class than either endemic or secondary subgroups. In many instances a number of factors could be considered as contributing to the failure of nutrition, but it had been possible to classify each case on the basis of the primary underlying cause.

Musser,³ reporting on the pellagra admissions to the Charity Hospital, New Orleans, for the years 1925 through 1931, found 751 cases in a total of 237,570 admissions, or an incidence of only 0.31 per cent. These were for the most part endemic cases, but some fell into the secondary and alcoholic groups.

J. S. McLester⁴ found that admissions for pellagra at the Hillman Hospital, Birmingham, Ala., represented 0.83 per cent of all admissions for the period from 1920 to 1933. These were largely endemic cases. Studies on a large number of pellagrins treated as ambulatory patients have been going on in the Nutrition Clinic of the Hillman Hospital for five years under the direction of one of us (T. D. S.) and although several thousand have been observed only a few were admitted to the hospital. It should be pointed out that these figures might indicate that pellagra is more rare in certain Southern hospitals than in those we are reporting. This is because pellagrins are not ordinarily admitted unless they are considered emergency cases in many Southern municipal hospitals. In former years, severe pellagra was considered hopeless and mild pellagra not a sufficient reason for hospitalization.

Two more series are available in Harris's textbook⁵ on pellagra. These include the records of Sydenstricker⁶ for a twenty year period at Atlanta, Ga., and those of Ruffin and Smith⁷ for a ten year period at Durham, N. C. By additional information for-

there was an average of 33 pellagrins for 1,800 ward admissions for each of the twenty years. The incidence of pellagra was 1.8 per cent. The figures of Ruffin and Smith were correlated with admissions to the medical wards. For the ten year period ended in 1939 there were 237 admissions for pellagra among a total of 26,279 admissions to the medical wards, an incidence of 0.9 per cent. At the Duke Hospital only about half of the pellagrins seen in the clinic were admitted. These figures are tabulated for comparison with the Cleveland and Cincinnati groups in table 3.

The figures in table 3 may be compared with those given by Raman⁸ for a general hospital in the Province of Madras, India. In this hospital it was found that pellagra accounted for 0.65 per cent of all cases admitted to the medical wards. This is only an indication of the worldwide prevalence of pellagra. Whenever this disease is sought, it is found among the debilitated patients of large hospitals.

From these figures we can readily see that pellagra is an important medical problem in all these hospitals. Furthermore, it is at once apparent that the disease is by no means confined to certain regions of the Ameri-

Monthly incidence of alcoholic and secondary pellagra as compared with endemic pellagra. The secondary and alcoholic groups are from this paper; the endemic group is taken from the report of Smith and Ruffin.¹⁰

can Southern states but is found in areas where it is not generally thought of as an important problem. The percentages are not comparable because the pellagra admissions are compared in part with medical admissions and in part with total hospital entries. This makes the figures compared with medical admissions appear high. In the Cleveland and Cincinnati figures, no cases of readmissions are included. This reduces the total number by about half. Nonetheless, one must conclude from these figures that pellagra is an important hazard in regions not considered to have a pellagra problem. The Ohio cases are preponderately secondary to organic disease or chronic addiction to alcohol, but many resulted from dietary restriction, whether obligatory, ill advised or wilful.

It must be emphasized that the number of cases in the tables indicate only a fraction of patients with vitamin deficiency. No persons with ariboflavinosis and neuritis are included. It was estimated by Goldberger that for every person with typical clinical pellagra there are from twenty to a hundred with varying states of inadequate nutrition. Even this proportion omits the vast number of people whose diet, though not actually deficient and responsible for no recognizable disease, is far from the optimum for best health and vigor. From our experience we can state that hesitancy to make the diagnosis of pellagra without the terminal triad of dermatitis, diarrhea and dementia has been costly in lives and has retarded understanding of the disease. In any vitamin deficiency state early specific therapy is

more valuable than that which comes later when the disease is advanced and appears in its textbook form. From a careful review of prodromal symptoms observed for varying periods before the cases became well established, we are learning to recognize a nascent deficiency syndrome before any physical sign is manifest. For these reasons we have made surveys of the nutritional status of patients in the medical wards of the Cincinnati General Hospital. In spite of the extreme difficulty of obtaining reliable information about the past diet, a rough classification is possible. Preliminary studies indicate a high proportion of patients whose nutrition ranges from borderline to obvious deficiency. History of prodromal symptoms or objective manifestations of nicotinic acid, riboflavin or thiamine deficiency have been found in approximately 10 per cent of a series of 345 medical patients admitted to the wards for some other condition.

While alcohol addiction, particularly if complicated by cirrhosis, was a frequent cause, gastrointestinal, cardiovascular and pulmonary disorders were the most frequent predisposing causes. Acute infections were important in precipitating the development of clinical signs of vitamin deficiency disease. In almost every case there were several factors militating against adequate nutrition: previous inadequate diet, anorexia, fever, alimentary tract disorders, vomiting, diarrhea, liver disease, cardiac failure and many other circumstances. This reemphasizes the complicated substratum on which pellagra is engrafted and helps to explain some of the many vagaries of this disease.

SEASONAL VARIATION

It has been known for a long time that the incidence of outbreaks of pellagra rises in the spring to reach a peak in the early summer. We have therefore examined our material for the month of admission with pellagra, or the month of its detection if it developed in the hospital. Careful review of the histories reveals that clearcut evidence of glossitis or erythema appeared four to six weeks before admission in most cases. In the chart we have compared the percentage of each type classed as primarily alcoholic (169) and secondary (63) cases in this series with a table based on many thousand endemic cases compiled by Smith and Ruffin.⁹ Our figures include the ten year period that ended with 1939, while those from Ruffin and Smith are for the first five years of the same period. Since the alcoholic and secondary cases from Ohio follow the same trend as the endemic cases from the Southern states, we believe that this reemphasizes the essential unity of pellagra of endemic, alcoholic or secondary origin first stressed by Spies and deWolf.¹⁰ It also suggests that factors other than summer sunlight are important in this seasonal tide in pellagra.¹¹ Besides variation in food, it will be important to investigate such factors as fluctuations in metabolism, bodily activity and infections for their influence on the pattern of seasonal incidence.

COMMENT

In this study we have presented evidence that typical pellagra, the hallmark of advanced disproportion between nicotinic acid amide supply and requirement,

is a serious problem in two large hospitals in Ohio. While our figures are not suitable for exact comparison with other reports, it is obvious that pellagra is prevalent in Northern states. We believe that variations in its reported incidence depend on variations in recognition as well as true prevalence. Furthermore, clinical pellagra indicates advanced breakdown in nutrition. As the visible part of an iceberg, it may be the signal of widespread but subsurface danger in population groups under consideration.

In the present state of our knowledge, it is not possible for the practicing physician to derive much help in diagnosis from the complicated laboratory procedures used in nutritional research. Pellagra, beriberi and riboflavin deficiency have been found whenever an intensive search has been made in hospitals caring for large numbers of patients with serious disease. Secondary pellagra is recognized as a potential menace whenever familiarity with its early manifestations parallels careful clinical search for its presence where it is apt to occur. Unwise use of alcohol and ill advised diets used for reduction of obesity, treatment of peptic ulcer or control of diabetes frequently predispose to pellagra. While a careful appraisal of the history of dietary deficiency is still subject to many pitfalls, it should direct attention to the nutritional status of persons in whom it may be impaired. This is imperative wherever a combination of obstacles is placed in the way of proper nutrition. Any chronic illness or acute febrile disease, in addition to disorders of the alimentary canal, liver, heart and lungs which decrease available food when it is most needed, should be adequate warning of an impending deficiency.

Surgical operations on persons who have been suffering from some disease itself interfering with proper nutrition are apt to precipitate clinical signs of a deficiency syndrome. Shock, hemorrhage, anesthesia, nausea, vomiting, infection and fever, large quantities of parenteral dextrose and physiologic solution of sodium chloride, which not only increase carbohydrate metabolism but may effect a diuresis wasting vitamin stores, all oppose normal nutrition. Deficiency diseases may occur as an untoward sequel of operations under such conditions.

SUMMARY AND CONCLUSIONS

The data in this paper are presented as a progress note in a study of pellagra and related vitamin deficiency disease begun by one of us twelve years ago. It is at once apparent that pellagra is widely prevalent. For the two Ohio hospitals studied typical pellagra was found in 1 to 2 per cent of the medical admissions. This figure was doubled when readmissions were included.

The true incidence of pellagra appears to be underestimated. This is due in part to failure to suspect, to recognize and to report cases. Shifting emphasis toward the early signs of deficiency has revealed a higher incidence than that indicated by such studies as we report here.

Typical pellagra is the response of individuals to advanced or severe deficiency of the antipellagra factor. Such cases represent only a small proportion of persons whose inferior nutritional status is a handicap which may prove perilous in the presence of other diseases. This study does not include the large number of persons in whom malnutrition manifests itself as ariboflavinosis or neuritis.

PRESENT KEY PROBLEMS IN TUBERCULOSIS

EDGAR MAYER, M.D.

AND

ISRAEL RAPPAPORT, M.D.

NEW YORK

The sharpest controversy is now focused on three problems in tuberculosis:

1. Is a negative or a positive tuberculin reaction more desirable?

2. Are the lesions developing in recently exposed young adults of "primary" or "reinfection" type?

3. From what point should one date the clinical incipience of tuberculosis?

With regard to these three questions, it is in the first place to be emphasized that they have arisen only recently and are the result of the epidemiologic conditions which have developed in our midst within the last generation.

Previously in most communities it was true for the vast majority of persons that they become positive tuberculin reactors by the time they reached adolescence; that, while primary infections occurred in childhood, progressive pulmonary tuberculosis developed mostly only in early adult age; that a latent interval of a decade usually elapsed between the time of the infections and the evidence of progressive disease.

Only since the development of pulmonary lesions in tuberculin negative young adults has been observed in direct consequence of recent exposure has the question arisen whether these lesions are of primary or reinfection type.

Only since progressive disease following exposure and conversion from negative to positive tuberculin reaction has become a common observation has the question arisen. From what point should one date the clinical incipience of tuberculosis?

It is our contention that a rational answer can be given readily to these questions, but the answer will be different according to the epidemiologic environment in question. Failure to consider the factor of the epidemiologic environment is at the bottom of most of the misunderstanding and dispute over these questions. It is particularly true that there is lacking appreciation of the role of the epidemiologic environment in determining the character of tuberculous infections and the evolution of these infections in the majority of persons in the community in question.

This thesis will be best understood when applied to the discussion of the three key questions. Before entering on the discussion, to aid understanding, I present a brief review of the epidemiologic background of tuberculosis in the form of a table which speaks for itself. All we need to add here is a brief comment on the epidemiologic environment now prevailing in this country to which the present discussion is essentially applied. It is important to know that while the country as a whole has already gone ahead a long way on the downgrade phase of the epidemiologic cycle, there are sections, areas and racial groups within the country and in the midst of our communities still showing features of a high level of tubercularization. It may be said that in these "nests" (Frost) tuberculosis is still at its epidemiologic peak. The differences between some already greatly detubercularized and some still highly

tuberculized groups are now much accentuated in a manner which should be clear from the table and the discussion of the three key questions which follows.

QUESTION 1.—Is a negative tuberculin reaction more desirable than is a positive one?

ANSWER.—A negative tuberculin reaction is more desirable in a nontuberculized environment while a positive one is more desirable in a tuberculized environment.

REASONS.—*Facts.*—Tuberculosis is all the more serious a disease, the less prevalent tuberculous infections are in the community in question. Conversely, the more tuberculosis there is in a community the more are infections tolerated without producing disease.

The greater the number of negative reactors in the community, the greater the clinical significance of the fewer positive reactions, because a greater proportion of the latter will represent infections severe enough to lead to progressive disease. Conversely, in a community

Features of Three Epidemiologic Phases

	Upgrade	Peak	Downgrade
Community	Virgin	Tuberculized fully	Detubercullization; focalization
Mortality	Rising	Highest	Declining steadily
Morbidity	Rising	Highest	Declining steadily
Resistance	Low but rising	High	Beginning to decline
Allergy	Low but rising	High, prevalent and permanent	Declining incidence evanescent character resensitization
Contact	Increasing	Widespread and severe	Declining, particularly in severity and frequency
Infection	Rising incidence	Prevalent before adult age reached	Declining incidence particularly before adult age
Reinfection	None	None, hardly ever before middle age	Rising incidence throughout adult age
Disease	Acute and subacute generalized forms	Chronic endogenous phthisis and chronic hematogenous forms	Chronic exogenous phthisis
Latency	Infrequent, short	Prevalent and long between primary and chronic pulmonary tuberculosis between bouts of hematogenous dissemination	Declining and shortening between primary and chronic pulmonary tuberculosis

where the great majority are positive reactors the clinical significance of the latter is much less, relatively speaking, as the greatest proportion of such reactions represent only recurring contact.

Contact is always dangerous to tuberculin negative adults because these are presumably coming from a nontuberculized environment. The danger is particularly serious if contact occurs in a highly tuberculized environment (tuberculosis institution, homes of patients with open tuberculosis). In adults who have grown up in a tuberculized environment a positive tuberculin reaction is a sign of an infection long overcome and hence an asset.

It should be remembered, however, that in very young adults a positive tuberculin reaction may be a sign of only recent first infection the outcome of which is still unsettled. There is evidence that added exposure during this early phase of the infection is not healthful and may be harmful.

Interpretations.—In highly tuberculized communities the opportunities for exposure are so constant and ubiquitous that everybody is infected already in childhood and continues to be exposed to reinfection throughout life. Universally the first infection is

severe. In most cases it is enough to give permanent allergy. In a relatively small proportion of persons in the community as a whole, but in a considerable total number of people, the first infection is severe enough to leave lesions which remain susceptible of reactivation under the various exigencies of life, which is the so-called endogenous reinfection tuberculosis. Morbidity and mortality from the disease are high in such a community but the fatality of tuberculosis, considering the prevalence of this infection, is low. There prevails obviously very strong resistance to tuberculosis which is manifestly based on properties acquired by the first infection, which includes allergy. The vast majority of tuberculin positive reactors are safe in such a community.

Tuberculin negative individuals are safe only in a highly detuberculized community, where they may long remain uninfected or where infections are of a very much less severe type. Severe type of exposure is liable to become rather harmful to tuberculin negative individuals. Recent observations have demonstrated that a larger proportion of tuberculin negative adults so exposed will develop progressive lesions than is the case with already tuberculin positive individuals. It has been a long established fact that boys or girls who come from less tuberculized rural sections and become overexposed in a highly tuberculized city often develop disease. In the new epidemiologic environment we are dealing essentially with the same phenomenon in a somewhat different form and wider scale.¹

QUESTION 2.—What is the character of the lesions that are developing now in recently exposed young adults? Are we dealing with "primary" or "reinfection" type lesions?

ANSWER.—In some instances we may be dealing with a truly first infection lesion. In other instances we may be dealing with lesions due to a recurrent infection. Both of these may have some features of a "primary" type yet follow the course of "reinfection" type tuberculosis; hence they cannot be told apart.

REASONS.—*Facts.*—True adult "primary" infections of identical course with childhood primaries ending up in calcified residues of the classic Ranke complex are not at all uncommon now when first infections have become postponed into adult age. "Primary-like" lesions produced by recurrent infections following evanescence of a preceding mild infection and its allergy are also quite common now. These too often end up in a residue which is in no way different from the classic calcified Ghon focus.

Progression to chronic pulmonary tuberculosis may occur now from truly "primary" but more often from the just described "primary-like" lesions, both of which represent exogenous fresh invasions.

Interpretations.—Under the present epidemiologic conditions a negative tuberculin reaction no longer indicates a noninfected state. Lesions arising after recent exposure in tuberculin negative individuals may now represent either true "primary" or "primary-like" recurrent infections. Not only is it impossible to tell these apart but there seems to be little reason for such separation.

In the first place our observations indicate that even recurrent infections with "primary-like" lesions may proceed to chronic phthisis not directly from the initial

¹ At this juncture may we point to our prediction (*The Journal*, Oct 12, 1940, p 1295), on the basis of the foregoing considerations, that a rise in tuberculosis mortality will soon have to be faced in this country. The current statistical data already available indicate clearly such a trend becoming manifest first in the greater population centers.

exogenous focus but rather indirectly from the lymphohematogenous secondary foci in the apical and sub-apical portions of the lungs. Then it is conceivable that in the present epidemiologic phase even true first infections might produce "reinfection type" rather than "primary type" tuberculosis. This is just what Israel and his co-workers have recently assumed.

If I understand these workers of the Phipps Institute correctly, they advocate the revolutionary step of discarding altogether the concept of "primary tuberculosis" built on the enormous amount of experimental pathologic and clinical work of two generations since Parrott, Kuss, Ghon and others. Current observations led these workers to the following three interpretations: 1. Tuberculous first infections, which occur now mostly in young adult life, rarely produce primary type lesions. 2. Young white adults of this country respond to first infection with reinfection type lesions. 3. The response to tuberculous infection is determined by the character of the individual resistance and not by the presence or absence of previous infection.

The last explains the first and second points of this concept, which may probably be best described as an immunobiologic explanation of the current changes in tuberculosis. Undoubtedly this concept has been inspired by the results of Lurie's experimental work, which has emphasized the role of natural resistance in determining the character of the infection.

The concept presenting epidemiologic causes for the changing features of tuberculosis is less revolutionary, more simple and yet far reaching.

That the character of infections should change with the changing epidemiologic cycle has been a long emphasized fact. It is expressed in the general concept that the character of the epidemic determines the character of disease in all infections. It stands to reason that tuberculosis is no exception to this rule. Indeed, Frost years ago sufficiently emphasized the changing aspects of the tuberculous infection with the shifts in the epidemiologic environment. The latter we believe is a more logical explanation of the currently observed changes in tuberculosis. Point for point the logic of the latter concept as against the former might be stated as follows:

1. In the first place it is more logical to assume that "primary complexes" have become too mild, transient and inaccessible to clinical demonstration than to say that they no longer occur. As a matter of fact there is direct proof of increasing mildness of "primary complexes" already in the past. The rising incidence of evanescent tuberculin reactions in recent years indicates their complete obsolescence.

2. In the second place, it is hardly logical to insist on the "reinfection type" character of any tuberculous lesion now when distinction between the "primary" or "reinfection" type is admittedly no longer possible.

3. Finally it seems more logical to assume that recent rapid shifts in the epidemiologic conditions have had a more profound effect on the incidence and conditions of exposure than on individual resistance. We readily concede that in the present epidemiologic cycle people evince more natural resistance but postulate that primary infections have become more obsolescent because the conditions of exposure have materially changed.

QUESTION 3.—From what point should one date the clinical incipience of pulmonary tuberculosis?

ANSWER.—In very acute tuberculous processes the point of clinical incipience may readily be fixed to coincide almost with the time of first infection.

In very chronic tuberculous processes the clinical incipience cannot be fixed even with the appearance of the first demonstrable lesion.

REASONS.—*Facts.*—Tuberculosis is a process the evolution and pathogenesis of which differ with the character of the infection, which in turn changes with the epidemiologic conditions. In the epidemiologic upgrade phase the process is so rapid that it may be said to begin with the first invasion of the bacilli and their beginning multiplication at the site. At the epidemiologic peak the process is still set in motion by the first infection, but its evolution is so insidious that between the infection and the first clinical symptoms the period of latency may be one of years or even decades. Finally in the epidemiologic downgrade phase the process may require more than one infection to set it in motion and the evolution period shows the widest range from a few weeks to many years.

Interpretations.—Whether it is more logical to date the onset of pulmonary tuberculosis from the time a healthy person has first begun to react to tuberculin than it is to date it from the time a lesion has first become demonstrable by x-ray examination in his lungs will depend on age and place. This refers to the age of the person and the epidemiologic environment from which he comes and is living in. In persons reared and living in a highly tubercularized environment a positive tuberculin reaction is only to be expected. Here x-ray lesions are more often only potential and by no means definitely established phthisis. The vast majority of such lesions found in people in such an environment are definitely known to undergo more or less complete resolution and ultimate healing without ever producing clinical disease.

In persons coming from a highly detubercularized environment a positive tuberculin reaction may at times mark already the onset of disease. More often, however, there is a latency period of variable length during which presence or absence of a demonstrable lesion in the lungs is no criterion for the time of onset of phthisis. On one extreme there will be cases with such acute clinical onset that even the first positive roentgenogram shows already too extensive involvement. On the other extreme there will be cases in which the lesion first becoming demonstrable in the lungs remains for many months or years unchanged until finally its breakdown gives rise to progressive phthisis very abruptly.

The practical significance of the foregoing may now be stated as follows:

1. The younger the individual and the more detubercularized the environment, the greater the clinical significance of a positive tuberculin reaction and the phthisical potentiality of x-ray lesions.

2. Young people attending tuberculous patients must be very closely watched. Tuberculin negative persons are especially in danger. Even the tuberculin positive persons, if young, may have become positive only very recently and therefore are still not out of danger.

3. Since one cannot now tell apart the primary from the reinfection type lesion, all newly discovered x-ray lesions in young adults must be treated as potential phthisis, i. e., by a period of observation under rest.

4. On the individual himself and the local epidemiologic conditions must depend in each case determination of the point from which a newly arisen positive tuberculin reaction should be considered merely a sign of infection or an indication of clinical tuberculosis in need of treatment.

AN EPIDEMIC OF COCCIDIOIDAL
INFECTION (COCCIDIOIDO-
MYCOSIS)

BURT L. DAVIS JR., M.D.

RUTH TANGIER SMITH, M.D.

STANFORD UNIVERSITY, CALIF.

AND

CHARLES EDWARD SMITH, M.D.

SAN FRANCISCO

An epidemic of coccidioid infection would have been inconceivable five years ago. Then the usually fatal coccidioid granuloma was the only recognized form of infection by *Coccidioides immitis*. During 1936-1938 Gifford¹ and Dickson² proved that this fungus more frequently produces mild infections. Many of us are still conditioned by the former conception of coccidioidomycosis as a deadly disease. We hope that the record of this small epidemic will emphasize the frequency and usually benign character of coccidioid infection in its endemic areas.

These endemic regions are, like the site of our small epidemic, semiarid with hot, dry and dusty summers and autumns. The most publicized is the San Joaquin Valley, the southern component of the great central valley, of California. Other parts of southern California, Arizona, Texas and probably New Mexico and Mexico are endemic centers. Sporadic cases have been reported elsewhere in North America and Europe. The only other known endemic area is the dry Chaco region of South America. Many investigators have associated these dusty, arid qualities with the theory that the infection is generally acquired by the inhalation of *Coccidioides* chlamydospores. These spores, which develop in the mycelial form of the fungus, are extremely infectious. The fact that coccidioidomycosis does not pass directly from host to host³ indicates that the endosporeulating spherules, characteristic of *Coccidioides* in man and animals, are not well adapted to disseminating the infection. These deductions explain other features of the epidemiology of acute coccidioidomycosis such as the maximal incidence in the dusty season,³ the rapidity with which the infection is acquired³ and the ultimate infection of more than three quarters of the long time residents.⁴ The previous recovery of *Coccidioides* from one set of samples of San Joaquin Valley soil⁵ is convincing corroborative evidence. The epidemic described here summarizes this entire epidemiologic concept.

The protean symptomatology of coccidioid infection is also illustrated in this outbreak. We now recog-

nize that the symptoms of an initial infection are variable. Cases are usually diagnosed "flu" or "bronchitis," although many rarer diagnoses are also made.³ In from 2 to 5 per cent of such patients erythema nodosum and/or erythema multiforme develops, a symptom complex known colloquially as "San Joaquin fever," "valley fever," "desert fever" or "desert rheumatism."

This first reported epidemic of primary coccidioidomycosis involved 7 out of 14 Stanford University students and faculty members. On the afternoon of April 26, 1940 this group of 10 graduate and undergraduate students together with 4 faculty members left the Stanford campus on a biology field trip to San Benito County, Calif.

San Benito County is 100 miles southeast of San Francisco astride the Coast Range Mountains. While many parts of the county are well watered and produce diversified crops, those portions on the eastern slopes are quite dry. The Panoche Valley, separated from the San Joaquin Valley only by a low range of hills, averages but 8 inches of rain a year. In the spring the region is suitable for grain raising and grazing, though in the hot parched summers and autumns the country is sere.

The first night the party camped near the highway south of Hollister, the county seat. The following day was devoted to scouring the hills and valleys and collecting a variety of specimens: insects, arthropods, reptiles, flowers and plants. The night of April 27 was also spent in the open in the San Carlos Mountains, part of the Coast Range. On the following day the group returned to Stanford University.

On May 6, O. C., a graduate student aged 21, felt feverish and weak but had little malaise. He tried to overcome his indisposition with strenuous workouts. However, his illness grew worse and on May 8 he reported to the Men's Health Service. Because of a temperature of 103 F. he was hospitalized by one of us. A roentgenogram of the chest, taken because of some suspicious "tinkles," revealed multiple circumscribed densities. Various diagnostic tests including blood cultures, sputum examinations and cultures, serologic tests and coccidioidin tests were performed but failed to reveal the cause of the illness, although 10 mg. of coccidioidin produced some erythema with induration.

In the meantime five of the other students became ill: R. R. also on May 6, A. S. on May 7, D. S. and W. G. on May 10 and B. M. on May 11. All showed roentgenologic evidence of pulmonary consolidation or other pathologic process. Tests with 0.1 mg. of coccidioidin on 2 (A. S. and D. S.) were faintly positive and on B. M. strongly positive. However, examinations of the sputum were incomplete and the cause of the epidemic remained unknown.

The condition of all except the first patient (O. C.) gradually improved. He failed to respond to treatment, continued to have a high fever and his roentgenograms appeared worse. On May 24 he was moved to the Stanford University Hospital in San Francisco for further diagnostic study. A test with 0.1 mg. of coccidioidin was repeated on May 26 and produced definite induration measuring 12 by 12 mm. in twenty-four hours. Gastric lavage was performed the day that the coccidioidin test was seen to be positive and a few suspicious spherules were seen. (*Coccidioides immitis*

This investigation was supported by a grant from the Rosenberg Foundation to the Stanford University School of Medicine.

6. A description of the roentgen findings on our students has been reported by R. A. Powers and D. J. Starks in Radiology 37:449-453 (Oct.) 1941, in an article entitled Acute (Primary) *Coccidioidomycosis*: Roentgen Findings in a Group "Epidemic."

was subsequently proved by cultures and animal inoculations.) Fluoroscopy and roentgenograms on May 27 revealed that a cavity had developed in one of the consolidated areas. Moreover precipitin and complement fixation tests on his serum were positive for coccidioid infection.

After the diagnosis of active coccidioid infection was established, blood was drawn for sedimentation and precipitin tests from the other members of the expedition who had symptoms. Specimens of sputum were collected from all who could furnish any. Coccidioidin tests were repeated on most of them.

On June 4 all 13 of the group who were still on the university campus (O. C. was in the Stanford University Hospital) were assembled. Histories were taken of the movements of each person while on the field trip

results. Three others of the faculty group had positive coccidioidin reactions but negative precipitins, normal sedimentation rates and entirely normal blood pictures. One (Professor A.) had taught for some time years before in Rosedale near Bakersfield in the San Joaquin Valley, where *Coccidioides* is endemic. Professor W., also with a positive coccidioidin reaction, had taught near Bakersfield at McFarland. While he was in the San Joaquin Valley, he had a severe respiratory illness which was diagnosed tuberculosis and was sent to a sanatorium for several months. However, tubercle bacilli were never recovered from his sputum and his illness may well have been coccidioid. Miss T., also with a positive coccidioidin test, had made many field trips in the San Joaquin Valley and in San Benito County. She recalled no respiratory or other "flu-like" illness.

and of any subsequent illnesses. Coccidioidin tests were performed on those who had not yet been tested, blood counts made, erythrocyte sedimentation rates determined and blood removed for precipitin tests. More sputum cultures were also obtained.

On the basis of the positive coccidioidin reactions, positive precipitin tests, rapid sedimentation rates, characteristic blood counts and densities in their roentgenograms, all 6 students who had been ill were judged to have had primary coccidioid infections. Four of the group had *Coccidioides immitis* recovered from their sputums. One other student, J. B., felt well but had a positive reaction to 0.1 mg. of coccidioidin, a positive precipitin test, accelerated sedimentation rate and eosinophilia, bringing the total to 7 infections. The remaining 3 students had been well, gave negative coccidioidin reactions, had normal sedimentation rates and normal blood counts (one had 8 per cent eosinophils) and their serums did not show precipitins. One of the faculty group (Mrs. F.) similarly gave negative

One of the most interesting aspects of the epidemic was the suggestion as to where the fungus could have been inhaled. The nature of the epidemic suggested that the infected students must have had a common massive exposure which the 4 negative to coccidioidin did not experience. The 3 coccidioidin positive faculty members might or might not have been exposed, previous studies having indicated that one infection apparently results in an immunity.

The way the groups traveled in their automobiles precluded dust from the road as the cause, since uninfected students were in each auto load. At night the blankets were laid directly on the ground, but the infections were so scattered that no common exposure could have been possible. The manner in which the groups worked in their specimen hunting obviated any possibility of a suitable exposure except for one occasion: When the expedition was in the Panoche Valley on April 27 it stopped along a creek bank to collect flowers and explore an abandoned quick-silver mine. Some one

observed a rattlesnake which crawled down a ground squirrel hole. O. C. began digging industriously. Later he recalled the occasion because the dust was so dense and he was in the thickest of it. He was assisted or surrounded by all the other students who were infected, and also by Professor W. and Miss T., who, it has been shown, apparently had experienced a previous infection with *Coccidioides*. However, the 4 giving negative reactions to coccidioidin (Mrs. F. and 2 of the 3 students) were not anywhere near the digging, and the third student, W., was not close at hand either.

Thus circumstantial evidence strongly implicated the vicinity of the rattlesnake hole. In August 1940 one of the recovered students guided one of us back to the spot. Specimens of the soil were collected and from them *Coccidioides immitis* was recovered.

COMMENT

Not only is the mechanism of coccidioidal infection verified but also is resistance to exogenous reinfection substantiated. The incubation periods, nine to fourteen days, are likewise in accordance with the range previously established.³ Among the cardinal symptoms and signs summarized in the accompanying table, the pain or "tightness" in the chest is the most useful in a differential diagnosis. It is to be noted that none of the patients had erythema nodosum or multiforme.

REPORT OF CASES

CASE 1.—O. C., a male graduate student aged 21, was born in San Francisco and lived there all his life except that from 1934 through 1936 he lived in San Mateo and since 1936 he has been at Stanford (Palo Alto), and also during some summer vacations. In the summer of 1938 he worked on an Associated Oil tanker on the Sacramento and San Joaquin rivers. He did not go inland farther than 2 miles. In the summer of 1939 he visited friends in Fresno on week ends. He has also made occasional visits around Tracy and a few trips through the San Joaquin Valley.

On May 6, 1940, nine days after returning to Stanford from his rattlesnake digging in San Benito County, he suddenly felt weak and feverish. However, he had no actual malaise and attempted to throw off the illness with a vigorous workout followed by a half mile swim. The following day, May 7, the fever persisted, his appetite left him and a severe backache developed which lasted until the next day. He also began to cough and the coughing continued for a month and a half. On this second day of illness, despite his feeling of weakness, he played football for two hours. On awakening May 8 he felt "jittery" and so weak that he could hardly climb out of bed. To the other symptoms was added a severe frontal headache; at last admitting he was ill, he consulted the Men's Health Service. When the patient's temperature was found to be 103 F. he was sent to the Palo Alto Hospital under the care of one of us (B. D.). That night he had a drenching night sweat, and severe night sweats persisted until the last week in June. The day after entry into the hospital severe "backache" recurred. The previous attack had been unaffected by breathing, but this time breathing and coughing exaggerated it, suggesting pleurisy. Suspicion having been aroused by "a few faint tinkles," a roentgenogram was obtained. It revealed multiple circumscribed areas of increased density. Sulfapyridine was given for five days. The temperature dropped but the development of nausea and a dermatitis necessitated the discontinuance of this therapy. When the fever recurred sulfanilamide was tried. The fever continued and the dermatitis returned, so the drug was stopped. Blood cultures, serologic tests, sputum examinations and cultures being persistently negative and coccidioidin tests being interpreted as equivocal, the patient was transferred to Stanford University Hospital in San Francisco on May 24. Sulfathiazole treatment was initiated (1 Gm. every four hours) but discontinued after three days and a total dosage of 47 Gm. because of increase in temperature

(to 103.6 F.), malaise, generalized arthralgia and dermatitis. Meanwhile, on May 26 the coccidioidin test with 0.1 mg. of coccidioidin became positive (12 by 12 mm.). *Coccidioides immitis* was recovered from stomach washings made the same day and repeatedly from sputum specimens obtained over a period of two weeks, the last successful attempt being on a specimen obtained June 11, more than a month after onset of the illness. Precipitin and complement fixation tests for *Coccidioides* were also positive. Roentgenograms and fluoroscopy on May 27 revealed a cavity in one of the consolidated areas. However, the defect rapidly closed. The blood count on May 28 showed 16,100 white blood cells with 68 per cent polymorphonuclear neutrophils, of which 36 per cent were banded cells, 8 per cent eosinophils, 2 per cent basophils, 21 per cent lymphocytes and 1 per cent monocytes. There were 4.91 million erythrocytes and 13.72 Gm. hemoglobin (80 per cent Sahli). The erythrocyte sedimentation rate was 26 mm. in sixty minutes (Cutler). After the sulfathiazole was discontinued his only complaints were fever, night sweats and cough. The cough gradually diminished during the early part of June and by June 21 had ceased entirely. At the same time night sweats stopped and by the end of the month his temperature remained normal all day. He returned home July 3 but was kept in bed until August 1. Then, since he had continued afebrile and his sedimentation index was only 7.5 mm. in sixty minutes (Cutler), he was gradually allowed up. He was permitted to return to Stanford in the latter part of September and carried his full research load without ill effect. Regression of the pulmonary densities as revealed by roentgenograms continues, though slowly, and no cavities are discernible. His sedimentation rate is consistently 1 mm. in one hour (Cutler's method).

CASE 2.—A. S., a female sophomore student aged 20, born in Germany, moved to Wisconsin in 1927 and to California in 1934. She remained in the region around San Francisco Bay and her only contact with the San Joaquin Valley was on two trips en route to other parts of the state.

On May 7, 1940, ten days after participating in the rattlesnake digging, she reported to the Women's Health Service with a complaint of backache radiating to the right side of the chest, relieved by infra-red light treatment. On May 8 she had fever and night sweats with some generalized aching. The third day, May 9, the backache and pain in the right side of the chest recurred with increased severity, and some discomfort was noted in the left side of the chest. These symptoms were accompanied by a nonproductive cough, anorexia and severe frontal headache. Taping reduced her discomfort slightly but infra-red treatment made it worse. Her temperature was 100.6 F. and she entered Palo Alto Hospital under the care of one of us (R. S.). There were no physical abnormalities, but roentgenograms of her chest on the day of entry revealed a rounded opacity in the parenchyma of the lung opposite the right hilus. The total white count was 20,550 with 86 per cent polymorphonuclear neutrophils, 9 per cent lymphocytes, 2 per cent monocytes, 3 per cent eosinophils (subsequently rising to 5 per cent; shown in table). The hemoglobin level was 80 per cent Sahli with 4,650,000 erythrocytes.

Sulfanilamide therapy was started the day of entry and 515 grains (34 Gm.) was given within the next ten days without appreciable effect. The pain in the chest cleared in two days but the anorexia, headache and dry cough persisted. On May 10 a rash resembling tinea corporis appeared on the buttocks but disappeared in two days after local application of tincture of iodine.

The temperature reached a maximum of 103 F. on May 10 and dropped thereafter. It persisted between 99 and 100 F. until June 1. On May 22 she was discharged from the hospital. Sputum cultures made while she was hospitalized yielded only a yeast. A coccidioidin skin test (0.1 mg.) was "faintly positive" on May 19. When repeated on May 29 the same test was strongly positive. Serologic tests on blood drawn June 1 and repeatedly thereafter indicated active coccidioidal infection. Although initial cultures were negative, *Coccidioides immitis* was recovered in the medical school public health laboratory by means of guinea pig inoculation of treated sputum collected June 6 and June 9. Anorexia persisted until June 1, and cough

and headaches lasted until June 18. Some weakness continued throughout the summer, but by September she felt quite well and had regained the 12 pounds (5.4 Kg.) that she had lost during her illness. Roentgenograms showed gradual clearing of the density. She remained well during the ensuing year.

CASE 3.—W. G., a male graduate student aged 24, was born in Ohio and lived there until he came to Stanford in October 1938. His only contact with the San Joaquin Valley was one trip along Highway 99 en route to Los Angeles.

On May 10, 1940, thirteen days after participating in the rattlesnake digging, he began to cough, lost his appetite, felt feverish and complained of a frontal headache and a sense of oppression in his chest without actual pain. A "tightness" in his chest remained for only thirty-six hours and malaise was mild and also transient. An occasional nonproductive cough persisted until June 13. The headache continued for only three days. Continued anorexia caused him to lose 6 pounds (2.7 Kg.). During the latter part of the first week of his illness nightsweats were so severe as to dampen his pajamas. The duration of the fever was unknown, but it must have been for at least one week. On May 20 he was called in by the Men's Health Service for a check-up which was being made of all members of the expedition. His temperature was found to be 100 F., so he was sent to the hospital for roentgen and laboratory examinations. The roentgenograms showed an increase in lung root density but no definite areas of infiltration. After three weeks of illness, he noted a considerable chilliness on arising but had no real chills at any time. There was no backache, sore throat or nervousness other than pruritus. Instead of having insomnia, he was tired and slept about sixteen hours a day for the first three days of the attack. On June 5 his appetite was well on the way back but was still not normal. Outside of occasional cough and extreme fatigue no other symptoms were present. A coccidioidin test with 0.1 mg. of coccidioidin on June 4 measured 30 by 30 mm. By the time he was asked to collect his sputum on May 30 scarcely any could be raised. *Coccidioides immitis* was not recovered. However, his sedimentation index of 20 mm. (Cutler) and his blood count were supporting evidence, as shown in the table. Serologic reactions of his blood, both positive complement fixation and heavy precipitins, were characteristic of primary coccidioidal infection. He rapidly regained his strength. By June 23 he felt fine and remained well during the ensuing year.

CASE 4.—B. M., a female senior student aged 22, was born in Washington and came to California as a Stanford freshman in October 1936. Her only contact with the San Joaquin Valley was on occasional trips to Yosemite and Los Angeles. Only once while on such a trip did she stop overnight in the valley.

On May 11, fourteen days after the rattlesnake excavating and while in Sacramento en route to Lake Tahoe, she had a sudden onset of chills, then felt hot and completely lost her appetite, all of which she attributed to the heat. These symptoms continued and when she reached Tahoe she was short of breath, a condition she attributed to the altitude. The following day she began to ache all over and had a severe frontal headache. The fever and anorexia continued, and in addition she had diarrhea, vomiting and vertigo. Returning to Stanford on May 13 with severe backache, a temperature of 102 F. and a cough, her condition was diagnosed as possible measles and she was sent to the Palo Alto Hospital. Physical examination was entirely negative except for the elevated temperature and a generalized ("somewhat urticarial" according to her attending physician) eruption on her legs and thighs, with a few lesions on her back. The lesions itched and were diagnosed hives. They lasted four to five days and recurred once again on May 25. The malaise became worse and she noted tightness throughout the chest. It was not actually pleurisy but it caused her to have shortness of breath. She remained in the hospital five days and then, with the cough diminished and fever ended, she was discharged. However, the malaise, insomnia, loss of appetite and headache continued, as did the nonproductive cough. Small blisters appeared on the palms of her hands May 17 and remained for three days, after which the skin peeled. The appetite began to return after

two weeks, the weight loss having been at least 5 pounds (2.3 Kg.). Headaches stopped May 25. When interviewed June 5, she still had this sense of oppression in the chest, considerable dyspnea, periods of backache and a dry cough. She tired readily and did not have her customary energy. A coccidioidin test with 0.1 mg. of coccidioidin performed May 24 measured 50 by 90 mm. By the time she was asked to collect her sputum, May 30, scarcely any could be raised. *Coccidioides immitis* was not recovered. However, her sedimentation index of 23 mm. (Cutler) and her blood count were supporting evidence. Roentgenograms taken May 24 showed two areas of density beyond the left lung root and at the left base. These findings assume even more significance in view of the considerable clearing by June 12 and complete clearing by August. Serologic reactions of her blood, both positive complement fixation and heavy precipitins, were characteristic of primary coccidioidal infection.

The cough continued until June 12. When seen June 21 she stated that only in the last two or three days had her appetite been good. She still tired easily and became short of breath but otherwise felt all right, though not as full of "pep" as usual.

During the summer she was very quiet. Her roentgenograms cleared (as previously noted) and the lost weight was regained by August. By September 30 she felt fully recovered. She carried a heavy schedule during the year and felt entirely well.

CASE 5.—D. S., a female junior student aged 20, was born in San Mateo, Calif. She resided there two years, then went to Sacramento for nine years and lived continuously in Berkeley thereafter (nine years) until she started to Stanford in October 1937. She was in the San Joaquin Valley in 1937 en route to Death Valley and once took a field trip to Yosemite by way of Los Banos.

On May 10, 1940, thirteen days after the rattlesnake episode, she had an abrupt onset of pain in the neck and anterior part of the chest, cough, loss of appetite and generalized aching. She also felt feverish. The fever and aching persisted for three days and on the third (final) day she went to the Women's Health Service, where she was diagnosed as having myositis. The pleurisy was fairly severe, first on the right side and then beneath the breast bone, and remained for one week. It then disappeared and recurred twice, the last time being May 26. Both recurrences were for only a couple of days with generalized pain. The severe pain in the neck also lasted approximately one week. The cough, accentuating the pain in the chest, was persistent and produced little sputum. After three weeks it gradually abated and at the same time her appetite began to improve. No loss of weight was detected. The patient had severe nightsweats on the night of May 12 but noted them only on that occasion. Her headache, which began the day after onset of her condition, was located on the right side of the head and continued throughout the summer. The only cutaneous lesions that developed were hives, which appeared over the buttocks at the outset and which recurred June 4. These cutaneous lesions itched and were not at all like erythema nodosum.

A coccidioidin test (0.1 mg.) performed May 24 was equivocal. Repeated June 4, it was definitely positive (10 by 10 mm.). *Coccidioides immitis* was recovered at the medical school by culture of sputum collected May 30. Roentgenograms, taken on May 24, showed heavy lung root markings with density spreading into the right upper lobe. By June 12 there was considerable clearing of this density, and a roentgenogram taken October 9 showed complete clearing except for a suggestion of lung root enlargement on the right. Her serologic tests were also characteristic of primary coccidioidal infection.

During the forepart of the summer she improved rapidly, but in the latter part of August there were three nights in which there were nightsweats. She tired readily but by the latter part of September, when the university reopened, felt quite well, having gained 12 pounds (5.4 Kg.). However, during the autumn quarter she studied hard and found that she lacked her former strength. She lost 22 pounds (10 Kg.) during this period. She had a mild attack of "flu" in December with a normal recovery. A year after her illness she felt entirely well.

CASE 6.—R. R., a female sophomore student aged 19, was born in Oklahoma. She never lived in Texas or Arizona but once stayed two weeks in Santa Fe, N. M. She first came to California when she entered Stanford in September 1939. At no time had she been in the San Joaquin Valley.

On May 6, 1940, nine days after witnessing the rattlesnake digging, the patient felt feverish, ached all over, had a severe headache and backache, pain in the left side of her neck and left side of the chest, completely lost her appetite, was nauseated and vomited three times. That night she had the first of a month long series of nightsweats. The symptoms did not abate but grew worse, and after two days (May 8) the pain in the back and chest was so severe that she reported to the Women's Health Service. Physical examination failed to disclose any positive conditions. She had been swimming the day prior to the onset and her condition was diagnosed as strained muscles from diving. She was given heat treatment and was taped. The taping partially relieved the chest pain, which was accentuated by breathing, but the heat only increased the discomfort. A slight nonproductive cough which began on May 7 became much more severe on May 11, but its persistence was matched by the scantiness of the sputum. A small cutaneous lesion which appeared on her chin May 9 was diagnosed as either impetigo or poison oak and cleared after nine days. Insomnia was another feature of the illness. After eight or nine days the pleurisy and backache diminished but the other symptoms persisted for three weeks during which time the patient lost 9 pounds (4.1 Kg.). On June 1 she still had an evening temperature of 100 F., but it then abated along with her malaise and anorexia. The cough and headaches persisted for another week.

On May 30, 0.1 mg. of coccidioidin intracutaneously produced a reaction measuring 60 by 80 mm. with vesiculation of 10 by 10 mm. From sputum obtained May 30 and examined at the medical school, *Coccidioides immitis* was recovered both by cultures and by animal inoculation. Roentgenograms taken May 27 showed an area of patchy density near the periphery in the right costophrenic angle and a similar area of homogeneous density under the second right anterior interspace. These densities had cleared only slightly by October 9. The accelerated sedimentation index (14 mm. Cutler) and 10 per cent eosinophils were typical conditions and the serologic reaction was characteristic of primary coccidioidal infection.

She was exhausted by slight exertion until the middle of June (five weeks after the onset). During the forepart of the summer her strength gradually returned, but in the middle of August she began coughing and the left base of her chest hurt for six days. Then the pain gradually departed and by the middle of September she felt fairly well except for frequent headaches. In the autumn quarter she grew steadily more tired and her geology field trips exhausted her. In December she had an attack of influenza and during the rest of the school year continued to feel below par. However, her sedimentation index remained normal (under 5 mm. Cutler) and her precipitin and complement fixation tests for *Coccidioides* became negative and remained so, indicating that the infection was quiescent.

CASE 7.—J. B., a female senior student aged 21, was born in Huntington Park, Calif. She had lived there all her life with the exception of four school terms at Stanford beginning in October 1936. There was no history of residence in the San Joaquin Valley but of occasional trips through the valley on Highway 99. Usually she traveled along the coast on Highway 101.

There was no illness after the return from the field trip except a slight cough with an indefinite date of onset (around May 20) and subsequent to a hayride. After the onset of the cough, she also had headache. However, there was not present loss of appetite or of weight, or generalized aching, fever, pleurisy, nervousness or insomnia. During the entire spring quarter she did not feel her customary "pep," but there had been no significant drop after the San Benito County trip.

A coccidioidin test (0.1 mg.) performed May 30, 1940 was strongly positive, measuring 60 by 80 mm. Although her slight cough was nonproductive, sputum was collected June 9 and June 14, but *Coccidioides immitis* was not recovered. A

roentgenogram taken May 27, however, showed a peribronchial density at the right base, which had disappeared by August 21. Moreover, an accelerated sedimentation index (13 mm. Cutler) and 6 per cent eosinophils were additional corroboration of coccidioidomycosis. Finally, her serologic reaction was characteristic of primary coccidioidal infection.

SUMMARY

Seven out of 14 university students and faculty members were infected with *Coccidioides immitis* on a field trip to a region adjacent to the San Joaquin Valley. All 7 and 2 of the others who apparently had been immunized by previous infection were subjected to a heavy dust exposure. The fungus was recovered from the soil which had been the source of the dust.

The infections of 6 of the 7 victims were accompanied by moderately severe symptoms which lasted from three to six weeks, but all patients recovered without the development of coccidioidal granuloma.

A SURVEY OF COCCIDIOIDOMYCOSIS AT CAMP ROBERTS, CALIFORNIA

ROBERT M. SHELTON, M.D.

1st Lieutenant, Medical Corps, U. S. Army

CAMP ROBERTS, CALIFORNIA

In the early months of the development of Camp Roberts, among the many cases of acute respiratory illness receiving treatment at the Station Hospital, 2 cases of primary coccidioidomycosis were discovered. Camp Roberts lies on the western slope of the Coast Range Mountains of California, separated from the San Joaquin Valley by that range, and since this area had not previously been known to harbor the disease as an endemic focus a survey was undertaken to determine the extent of the disease locally, the results of which survey constitute the body of this report.

INTRODUCTION AND HISTORICAL DATA

Dr. Emmet Rixford of San Francisco reported in 1894¹ a case of malignant ulcer of the skin caused by an agent which he and Gilchrist² named *Coccidioides*. This was the first report of this disease entity in the American literature, though the same disease had apparently been described in 1892 by Posada in Argentina. The infecting agent was a tiny spherule which multiplied by endosporulation and was capable of producing an ulcer if rubbed into the abraded skin of a dog; it was named *Coccidioides* because of its resemblance to *Coccidia* of animals. At first thought to be a protozoan, it was reported in 1900 by Ophuls and Moffitt³ to be a fungus, readily cultured on various mediums. The disease coccidioidal granuloma proved to be a serious disorder, involving not only the skin but also many of the other viscera and leading to a fatal outcome in 50 per cent of the cases.⁴

By 1936 450 cases of coccidioidal granuloma had been reported in California, constituting the majority of all the cases on this continent. A striking feature was that most of the patients had lived a longer or shorter period of their lives in the San Joaquin Valley of California. The disease had been discovered in animals, as well as

in man, and pathologic investigation showed that the probable port of entry in most cases was the respiratory tract, with involvement of tracheobronchial and mediastinal lymph nodes, much the same as in tuberculosis. In fact, the mimicry of tuberculosis was striking in all phases and progress of the disease.

An important further step in the understanding of the infection was made by Gifford⁵ and Dickson⁶ during the period 1936-1937, when they proved that *Coccidioides* was the cause of a syndrome known colloquially in the San Joaquin Valley of California as "Valley fever" or "San Joaquin fever." This syndrome, previously well known but not understood, was characterized by the development of erythema nodosum and attendant systemic symptoms much like those of influenza. *Coccidioides* was cultured from the sputum of many patients and all were found to react positively to a cutaneous test with coccidioidin, a substance closely analogous to tuberculin. It was determined that "valley fever" was associated with the initial infection with *Coccidioides* and is the analogue of "childhood" tuberculosis. The name "primary coccidioidomycosis" was given to this symptom complex by Dickson.

Since then it has become clear that a majority of the residents of the San Joaquin Valley eventually become infected (70 to 80 per cent give positive reactions to the coccidioidin skin test after ten years' residence); that 2 to 5 per cent of those infected have the erythema nodosum syndrome known as valley fever,⁷ whereas the remaining 95 to 98 per cent may be entirely asymptomatic but generally have respiratory symptoms frequently confused with influenza; that the granuloma or secondary stage (like "adult" tuberculosis) is, fortunately, quite rare, and that the San Joaquin Valley is not the only endemic focus but shares its stigma with parts of Arizona and Texas. Argentina and possibly even Italy and other continental areas had been implicated previously. Exactly what percentage of those exposed develop skin sensitivity to coccidioidin or manifest the symptoms of primary coccidioidomycosis is not known. Nor is there any exact information as to the reservoir from which the fungus comes to enter the human being, but it is presumed from the high correlation of frequency of new cases with dryness of the atmosphere that the soil harbors the fungus and gives it up as dust that may be inhaled. There is no information as to what percentage of those infected eventually have the dread granuloma, but its infrequency can be seen by the fact that while a large percentage of the population of the San Joaquin Valley (estimated population 750,000) is apparently infected with *Coccidioides* (sensitive to the coccidioidin skin test), the Department of Public Health of the State of California⁸ reports an average annual incidence of only 46 new cases of coccidioidal granuloma. Susceptibility to the development of the granuloma is relatively high among the dark skinned races, and it is of note that cases of the granuloma show a much lower degree of skin sensitivity to coccidioidin than do those who have recovered from the initial infection without apparent residual disease.

MATERIAL AND TECHNIC

This report is based chiefly on the results of two skin test surveys made three months apart, the two surveys being made on the same group of persons, with a view to finding in how many instances the test became positive during the three month interval. In addition, there are reports of 3 cases discovered in the hospital—not a part of the survey.

Coccidioidin supplied by Dr. C. E. Smith of Stanford University School of Medicine was diluted with saline solution to a concentration of 1:1,000. While it is conceivable that 1:100 dilution would show sensitivity occasionally where 1:1,000 would give a negative or questionable response, it has been found that for practical purposes 1:1,000 is sufficient. The same bottle of undiluted coccidioidin was used as the source in the two series of tests, being kept during the interval in a refrigerator.

It cannot be said that a precisely constant amount of the antigen was injected in each patient. The necessity of doing the procedure with minimum delay required a special "mass attack" technic, and the amount of fluid lost in the hub of the needle and in expelling air bubbles prevented accurate measurement. The amount injected was determined by gross inspection of the wheal produced and averaged 0.05 cc. In no case was it more than 0.10 cc. nor less than 0.03 cc. It is my observation that the variation in amount, within the limits men-

TABLE 1.—Results of Coccidioidin Skin Tests

	Number

Men tested	888
Positive	11
Second test, Sept. 13, 1941	
Men tested (less positives from first test)	776
New positives	14

tioned, is not significant except perhaps in distinguishing slight variations in the grade of the reaction. In other words, the positive reactors will appear in response to 0.03 cc. as surely as to 0.10 cc. but may be graded "one plus" with the former and "two plus" with the latter.

The two series of tests were made on a battalion of men plus a few men from three other battalions newly arrived at Camp Roberts. The first test series was done June 21 on a battalion of troops that had arrived between June 12 and June 15. The troops were gathered from the Middle West—Illinois, Missouri, Nebraska, Arkansas and Texas—and no attempt was made to list them by residence except for those who reacted positively to the first test.

The second series of tests was made on the same men on September 13 after three months of training in and about Camp Roberts and just before their transfer to other camps.

All reactions were read at from forty-four to forty-eight hours and were recorded thus:

± definite induration and erythema but less than 1 cm. in diameter.

+ induration of 1 cm. in diameter.

+ + induration of 1 cm. in diameter plus flare of erythema of 1 cm. or more.

+ + + induration of 2 cm. or more.

+ + + + vesiculation

Those reacting positively to the second test who were previously demonstrated to be nonreactors were questioned regarding symptoms during the three month

interval, and roentgenograms of the chest were made. All were carefully questioned regarding visits to other localities during this time.

In some cases, specimens of the blood were sent to the Department of Public Health and Preventive Medicine of the Stanford University School of Medicine in San Francisco for serologic tests. Under the supervision of Dr. C. E. Smith the specimens were examined for the presence of precipitins and for complement fixation according to technics described elsewhere. In 1 case, sputum was forwarded to Smith for culture and animal inoculation, since the final determination of the nature of the fungus depends on its ability to produce the typical reaction in animals.

The author wishes to express appreciation for the invaluable aid given by Dr. Smith and also by Lieut. Col. William Levin of the Sanitary Corps, Lieut. Col. Warfield W. Lewis of the infantry, Private Dernbach and others. Each of these rendered service without which this work would have been entirely impossible of achievement.

RESULTS OF SURVEY

The first series of tests was accomplished on 888 men. Eleven were found to give a positive reaction, though they had been at Camp Roberts too short a time to have picked up the disease here (tables 1 and 2). Of these positive reactors, 1 had lived only in Montana and Idaho, 1 had lived only in Arkansas not far from Texas, 6 had lived in Texas and 3 had lived in the San Joaquin Valley of California. Texas and California are already well recognized endemic foci of the disease, and the reaction in the first case suggests the possibility that Montana or Idaho may harbor the disease.

The second series included only 736 of the 877 who gave a negative reaction to the first test, because many of the men were not available, being on leave or having been transferred. Actually, of the 11 found positive in the first test, 8 were retested and all reacted positively the second time. Of the 736 men in the second series, all negative to the first test, 14 gave positive reactions. In other words, 14 men proved to be nonreactors in June reacted positively in September. Three of these had visited in the San Joaquin Valley during their stay at Camp Roberts, 7 had been to Los Angeles or San

Francisco and 4 had not left the vicinity of Camp Roberts more than a few miles, having gone to Salinas (1 case), Pismo Beach (1 case) and Paso Robles (2 cases) (table 3).

Of the 14 positive reactors, only 1, according to a check in the hospital records and answers to a questionnaire, had entered the hospital for any febrile or respiratory illness, though hospitalization is the routine procedure for any illness severe enough to prevent exercise of full duty. It is obvious that the onset of the

infection was not attended by the development of distressing symptoms in most of the cases.

All but 4 of the 14 felt that they had at one time or another during the three months had a bad cold or influenza, and 3 had noticed a cutaneous eruption—nonitching red spots that looked like the positive reac-

tions to the skin test. None of these eruptions had been examined by medical officers, so their description had to be a yes or no response to a questionnaire which was sent to all positive reactors (see table 4).

Roentgenograms of the chest made September 16 on the 14 new reactors showed 1 case of pulmonary infiltration, a small area of light, uniform density much like the pulmonary manifestations in "childhood tuberculosis," and 2 cases with moderate enlargement of hilar lymph nodes. Check-up films of the 14 cases found on survey have not yet been made, and the results will be reported later.

REPORT OF CASES

Although many patients with primary coccidioidomycosis are entirely asymptomatic and must be searched out with the aid of a skin test survey, a few are ill, with symptoms like influenza or a bad chest cold. It was one such typical case that called our attention to the presence of Coccidioides in this location. The clinical summary is presented herewith:

CASE 1—H. D. S., a white man aged 23, entered the hospital April 29, 1941 complaining of a cold and cough for three days, headache for two days and chills and fever for one day. Except for a temperature of 38.2 C (100.8 F.), there was no abnormality apparent. The second day, the temperature went to 39.2 C. (102.6 F.) and the cough was worse, but three days later the fever was gone, the patient felt well and he was returned to duty. Five days later, May 8, he reentered the hospital because of pain in the right side of the chest of three days' duration and persistence of the cough. The temperature was 37.9 C. (100.2 F.) and there were rales at the right apex. The fever, cough and chest pain subsided a little but were still present after five days, at which time the white blood cell count was 12,300, with 50 per cent neutrophils, 32 per cent lymphocytes and monocytes, 12 per cent eosinophils, and 6 per cent basophils. The possibility of the trouble being tuberculous was considered and a roentgenogram of the chest was made, showing a fanlike area of increased density extending from the hilus to the right apex. In order to clarify the situation, a skin test with tuberculin was made and a coccidioidin test was done at the same time. After forty-eight hours, the tuberculin test was negative, and there was a definitely positive reaction to the coccidioidin (1 cm. by 1.5 cm. induration and erythema). The most startling development was the appearance at this time of erythema nodosum, a crop of red indurated spots on the legs, which had actually started two days previously and subsided gradually in a period of five days. The blood count was repeated, showing 10 per cent eosinophils, and a specimen of blood drawn June 7 was sent to Dr. C. E. Smith, who reported strong reactions to precipitin and complement fixation tests, "findings characteristic of moderately severe primary infection due to Coccidioides immitis." Clinically there was gradual improvement, a roentgenogram on June 6 showed almost complete resolution of the lesion previ-

ously noted and after a month of hospitalization and symptomatic therapy the patient was again returned to duty. No sputum culture was made. This man had lived in Nebraska prior to induction into the Army and had not been more than a few miles away from camp after his arrival here.

Another summary is presented to illustrate the severity of the symptoms in an occasional case and the difficulty in arriving at the proper diagnosis:

CASE 2.—E. R., a white man aged 24, entered the hospital Sept. 2, 1941 because of severe pain in the back which had appeared suddenly two hours previously while the patient was sitting at a table. For a few minutes he could hardly move, the pain was so severe, and he lost no time in getting to the hospital by taxicab. The pain was located in the lumbar region and was aggravated by respiratory movement or bending of the trunk. On entry there was evident pain and guarding of the muscles of the back, with impairment of the movements of respiration and bending of the trunk. There was no fever, the pulse rate was 88 and the blood pressure was 124 systolic and 80 diastolic. He was given sedatives and the clinical impression was that he suffered from an acute myositis secondary to chronic prostatitis. On the fourth day the temperature rose to 37.8 C. (100 F.), though the pain in the back had practically disappeared. Two days later the temperature was 38.3 C. (101 F.) and consultation was requested. In the next five days the temperature went gradually up to 40.7 C. (105.2 F.), with no symptoms except those of fever, and the patient was seen by eight different physicians, with diagnoses of pleurisy, pulmonary tuberculosis, pulmonary infarct, prostatitis, perforating ulcer of the duodenum, dissecting aneurysm, renal stone, bronchopneumonia, malaria, mediastinitis, undulant fever, typhoid, pyelitis and perinephric abscess. During this time he underwent lumbar puncture (the spinal fluid was normal) and catheterization (the urine was sterile); he was examined roentgenographically four times (no abnormal findings) and the following laboratory procedures were done: an electrocardiogram was made, a culture of the urine was taken, six routine urinalyses were made, six routine blood counts were made, the sputum was examined, a blood smear was examined for malaria, agglutination tests were done for evidence of undulant fever and for the typhoid-paratyphoid group and a stool culture was made. The red blood cells numbered 4,000,000 to 4,500,000 per cubic millimeter, the white blood cells 6,600 to 11,200 with from 56 to 80 per cent polymorpho-

was recovered, proved by culture and animal inoculation. The patient made a complete symptomatic recovery and was discharged from the hospital three weeks after entry. It is noteworthy that he did not manifest erythema nodosum at any time. He had spent all his life in Alabama, had never been out of the state prior to induction into the Army and since coming to Camp Roberts had made one trip to San Francisco, none to the San Joaquin Valley.

One patient was seen in the hospital as presenting a dermatologic problem:

CASE 3.—E. O., a white man aged 22, entered the hospital May 26, 1941 because of red spots on his legs of two days' duration. The eruption was somewhat tender and caused his legs to feel swollen. He had been in the hospital two weeks previously for pain in the chest, aggravated by breathing deeply, associated with a fever of 38.3 C. (101 F.), and had been released after one week, at which time he was afebrile and asymptomatic. The cutaneous lesion was typical erythema nodosum and the probability that it was a manifestation of coccidioidomycosis was considered. A roentgenogram of the chest showed a small patch of infiltration in the base of the right lung, and there was eosinophilia (18 per cent). The eosinophils two days later were recorded as 13 per cent. A coccidioidin skin test with the usual 1:1,000 dilution gave a very weak response, and the test was repeated with 1:100 dilution, giving a strongly positive reaction. This weak response to the coccidioidin is very unusual, since patients with erythema nodosum are notorious in the vigor of the sensitivity of their skin. Serologic reactions on the patient's blood, done by Dr. Smith, were strongly positive.

The erythema nodosum cleared in ten days, leaving only a brownish discoloration. The chest symptoms were of no concern, and the patient returned to duty. He had lived in Minnesota all his life prior to coming to Camp Roberts and after his arrival here had been no farther away than San Luis Obispo.

COMMENT

The chief significance of the investigation here reported is the demonstration of the fact that coccidioidomycosis can be acquired in the environs of Camp Roberts, California, a hitherto unknown endemic focus. This fact has been proved by the finding of 14 persons who were known to have given negative reactions to the coccidioidin skin test on arrival here and positive reactions three months later. It might be said in criticism of this statement that (1) the positive skin test is not specific but may have developed in response to some factor other than the exposure to *Coccidioides*, (2) the proved exposure may have taken place before arrival at camp, as while traveling across the country, (3) the proved exposure may have been acquired after arrival here but while visiting in some nearby area such as the San Joaquin Valley. In refutation of these criticisms it must be pointed out (1) that the skin test has apparently been proved to be quite specific, as determined by its use over a period of years, (2) that, while it must be admitted that some of the men may have been exposed to the disease en route to Camp Roberts the possibility of this is slight and (3) that careful questioning regarding trips to other localities after arrival here demonstrates that in at least some of the cases the exposure must have been here. Three of the 14 had visited in the San Joaquin Valley, 7 had been to Los Angeles or San Francisco but had not been in the San Joaquin Valley and 4 had not left the vicinity of Camp Roberts more than a few miles, the actual far points being Salinas, Pismo Beach, Paso Robles and San Miguel.

By extrapolation, if it is assumed that the percentage of men found infected is uniform throughout the camp, it could be estimated that, of the 20,000 to 25,000 men here, from 400 to 500 acquired primary coccidioido-

nuclear neutrophils and as much as 16 per cent eosinophils. All other tests were negative. On September 15, two weeks after entry, the clinical impression was that the disease was most likely tuberculosis of the pleura and hilar lymph nodes but possibly coccidioidomycosis, and a coccidioidin skin test was done. The reaction was brisk and violent, with vesiculation of the skin. Blood was drawn and sputum was collected for examination at Stanford, with a report of unusually strong and rapid precipitin reaction and positive complement fixation in the serum "characteristic of active coccidioidomycosis being well handled." From the sputum viable *Coccidioides immitis*

mycosis between June and September of this year. Observations elsewhere indicate that the incidence of new cases is highest in the dry months, falling to almost nothing in the wet winter months, so that the number of cases developing in three months of the summer represents nearly half of the annual incidence.

One feature of interest is the sporadic nature of the infection. The men tested in the two series were grouped almost equally into four companies, but the new positives were all in two of the companies, the other two companies being entirely free of new cases. Three of the new positives were White, Whitfield and Wilson, alphabetically contiguous on the company roster and presumably together on many bivouacs and maneuvers. It is possible that all were infected by the same gust of wind, carrying dust from a particularly heavy growth of the fungus.

Of the 14 men with proved new coccidioidomycosis, only 1 had entered the hospital for a respiratory or febrile illness. Two others had been hospitalized, one for a head injury and one for flat feet. There is no provision at Camp Roberts for resting off duty. If a soldier is not feeling fit for strenuous duty he enters the hospital. It is therefore obvious that the morbidity associated with the onset of coccidioidomycosis is almost insignificant in most cases. Some of the patients, however, suffered illness sufficient to incapacitate for military duty. In fact, the discovery of the presence of coccidioidomycosis at Camp Roberts depended on the typical symptoms occurring in one of the early patients.

When symptoms do occur in association with the onset of the disease, they may be of great diversity. Apparently there may be any combination of the various "typical" stigmas, and any grade of severity may exist. The symptoms considered characteristic include malaise, weakness, fever, chills, chest pain, cough and dyspnea, and the common manifestations include erythema nodosum, erythema multiforme, pulmonary rales, roentgen evidence of pulmonary or mediastinal lymph node disease and eosinophilia. Of course, a positive coccidioidin skin test may be presumed to exist in all new cases after the first five to fifteen days. The presence of a positive skin test, however, does not necessarily indicate a recent or active stage of the disease.⁷ Like the reaction to tuberculin, the skin test is positive for many years after the primary infection, presumably for life. Serologic evidence of the disease, in the nature of a precipitin reaction or a complement fixation, is present in the vast majority of cases; at least, in all our cases in which the tests were made they were found positive. The sputum yields the fungus itself in approximately 50 per cent of cases of erythema nodosum of coccidioidai etiology, according to other investigators.⁷ Detection of the fungus requires culture of the sputum and inoculation of guinea pigs or mice with any suspicious growth, because direct microscopic examination of sputum or colonies from primary culture does not provide any sure differentiation from other fungi. While the final proof of the diagnosis depends, of course, on the recovery of the etiologic agent, for practical purposes diagnostic error is minimal if the skin test, eosinophilia, pulmonary signs and symptoms and skin manifestations are typical.

SUMMARY

1. Several cases of primary coccidioidomycosis developed in the vicinity of Camp Roberts, California, a hitherto unknown endemic focus of the disease.

2. Of 736 soldiers who came from other parts of the United States to Camp Roberts, 14 became infected during three months' residence here, from June to September.

3. The morbidity associated with the onset of infection is almost negligible in most cases.

4. Rarely a patient becomes quite ill at the onset of the disease, with more or less fever, cough, pain, cutaneous eruption and pulmonary infiltration.

OBSTETRICS IN WARTIME

O. LEE SCHATTENBURG, M.D.

Acting Director, Bureau of Maternal and Child Health, Board of Health, Territory of Hawaii

HONOLULU, HAWAII

On Sunday morning Dec. 7, 1941, out of literally a clear sky, Honolulu and its environs suddenly suffered a severe bombing. The details of the damage done, the number of civilian and military casualties and the military aspects of the problem are not the purpose or province of this paper. The sudden violence of this catastrophe did awaken the world to the possibility that a similar event might happen almost anywhere else.

Much will be written and much will be said regarding the care of casuals, emergency aid stations, police and fire protection and a number of other phases of community activity under similar circumstances: the specific problem of this paper is to consider obstetric management under crisis conditions. It is probable that this problem is just as real as the aforementioned problems; it is also probable that this problem as it existed in Honolulu would be paralleled in any other community. The experiences of this community are therefore delineated here in the hopes that they may be of help and guidance to other communities in making plans for war time conditions or a possible sudden catastrophe.

PEACE TIME SETUP

Hawaii is a group of islands and therefore a scattered community with problems of transportation much greater than in most mainland communities. Honolulu is the only metropolitan area with a population of 200,000; the rest can be accepted as essentially rural with highly organized plantations making up the bulk of the latter. The 400,000 odd population gives birth to about 10,000 babies yearly; this is a very mixed population, nearly half being Orientals. Oahu is not the largest island, but it contains the bulk of the population and nearly all the military activities, personnel and defense equipment; it was this island which was the target for the Japanese attack.

Numerous factors contributed to a very poor obstetric record in this community until about a decade ago. At that time the outstanding facts showed, briefly, that:

Almost 50 per cent of deliveries were unattended.

Only 25 per cent were hospital deliveries.

Less than one third of deliveries were by physicians.

Maternal mortality rates ranged around 9 per thousand live births.

Infant death rates were around 90; they had previously been consistently over 200 in some communities.

Nobody had any control over midwives, and there was no one to question their qualifications or abilities.

There was no regulation of hospitals accepting maternity cases.

Almost every physician was doing some obstetrics, and there was no one to question his methods or end results.

Antepartum care was the exception rather than the rule.

The advent of a maternal and child health program under the board of health proved very useful as a state agency in effecting improvements, and about it could be built a sane and practical program of maternal welfare. With an obstetrician and a pediatrician at the head of such a bureau, many accomplishments were recorded which tended materially to change the obstetric complexion. In contrast with the conditions of ten years ago, the following briefly shows the present status:

About 80 per cent of deliveries occur in hospitals.

More than 80 per cent of deliveries are attended by a physician.

The maternal mortality rate is 1.9 per thousand.

The infant death rate is around 40.

Less than 10 per cent of deliveries are unattended.

Midwives are under strict control by the board of health; there are fewer midwives, and midwife deliveries are decreasing in number.

There are forty antepartum clinics, carefully supervised, offering services even to remote communities.

Antepartum care is the rule rather than the exception.

An educational program has taught the expectant mother to demand hospital deliveries by a physician.

All hospitals accepting maternity cases are inspected yearly. They have been compelled to come up to minimum standards of equipment and service (separate nurseries, incubators, delivery rooms, isolation facilities, 75 square feet per adult bed, and so on).

Obstetric consultation services are offered by qualified obstetricians.

Each maternal death is carefully investigated.

Refresher courses in obstetrics and other teaching methods have awakened the general practitioner to his responsibilities in his obstetric practices, with noticeable improvement.

With this record of achievement, it is logical that the state agency should be in a key position to make plans for a major disaster and to help execute such plans when catastrophe arrives. Any community now making similar plans might do well to consult its own state agency, because it is in the best position to have a broad perspective of the community problems.

DISASTER PLANS

Honolulu had realized its precarious position and had probably gone further in perfecting major disaster plans than most similar mainland communities. With "M-Day" funds set up through legislation and headed by a major disaster council, months of planning and training found Honolulu with plans which came in handy when catastrophe overtook us suddenly. Of all the civilian groups, the medical fraternity was probably best prepared. This is proved by the facts that within about an hour's time after bombing began the following medical activities were in evidence:

First aid stations, completely staffed with doctors, nurses and litter bearers, were at their stations and functioning throughout the city; although the equipment was inadequate at first, the personnel were adequately trained in their duties by many weeks of first aid instruction.

Civilian surgeons with previous instruction in military surgery were immediately available for civilian hospitals and the surplus of doctors was rushed to a military hospital, where they proved useful in caring for a large number of casualties.

(The physicians had previously been carefully catalogued regarding their special abilities, training and whereabouts.)

By previous arrangement, many station wagons and light trucks were immediately available for ambulance service. A corps of trained women drivers proved very useful.

Equipment for producing plasma and a plasma bank of about two hundred flasks were available through previous foresight and proved most useful. The equipment was immediately put to further use and the plasma bank has now been built up to about five thousand flasks.

Civilian hospitals were immediately expanded to maximum capacity by adding stored equipment and by evacuating the less ill patients to their homes. The precision with which civilian hospitals functioned was the reward of careful planning and previously trained personnel.

The board of health immediately went on a twenty-four hour basis to lend every effort in safeguarding the health of the community.

While a sudden disaster instinctively turns one's mind to the importance of first aid, of immediate care of casualties, of ambulances and trained personnel to care for the wounded, it is also well to keep in mind that, war or no war, women will keep right on having babies and they must also receive adequate care. What is more, the experiences in London showed that, under the acute stress of a bombing, women are apt to go into premature labor or to abort. Plans for a major disaster must therefore include obstetric provisions.

Locally our plans had been directed along several practical lines and, fortunately, had had some time to mature before the crisis hit us. The following proved to be very workable:

1. Obstetricians were assigned to maternity hospital posts instead of being used in other hospitals to care for casualties.

2. Pediatrician-public health nurse teams, equipped with incubator, oxygen and other equipment, were available for premature infants born before getting into a hospital.

3. A careful survey of all available maternity bed facilities in the community had been made and had proved the fact that such facilities were already overtaxed; there had been a rapid increase of population as the result of importation of defense workers and increasing military personnel. The sudden crisis caught us before we had been able to expand our maternity facilities, and it became obvious that to increase the obstetric load was possible only by decreasing the stay post partum. Our patients were therefore forewarned that, in case of a disaster, we would continue to offer the facilities of our delivery rooms but would expect them to return to their families earlier than under normal conditions.

4. Arrangements were made with the hospitals to prevent the encroachment on the maternity departments by casualties.

5. All public health nurses were given a refresher course in practical obstetrics to improve their efficiency in home deliveries.

6. Home delivery packs were made up and kept in readiness in a convenient place for district nurses or doctors.

7. Nursing personnel in obstetric departments should be kept intact regardless of the extra load the rest of the hospital might suddenly be compelled to carry.

8. All expectant mothers were repeatedly advised to continue planning for hospital deliveries, regardless of a crisis.

9. Competent pediatricians and obstetricians were to be kept available for consultation purposes as an aid to the general practitioner or to cover for him in case he was suddenly pressed into other disaster activities.

10. Prompt resumption of all obstetric and pediatric clinics was planned for as soon as circumstances possibly would permit.

HOW THE PLAN WORKED

With surprising ease, the obstetric load was carried with the minimum of friction. Postpartum patients were evacuated to their families without any protests. The delivery services and nursing facilities were adequate. The surprising fact, however, was that we did not get the flood of premature labors or abortions which were expected; there was a slight flurry the first day or two, but the incidence was hardly above normal. This can possibly be explained by two underlying factors: (1) The bombing came as a sudden surprise, giving us no time to develop the state of alarm that would accompany anticipation of such an event, and (2) the quality of American womanhood of today is such as to be able to face a real crisis with remarkable fortitude. The latter is an observation we have been able to make repeatedly in private and clinic cases and seems convincing that the mother of today instinctively retains some of the courage which allowed pioneer women to continue to rear their families in the face of hardship, privation and danger. However, it is fully appreciated that a second bombing here would be a much more severe test of fortitude than was the first and we are continuing to expect an increased load of abortions and premature labors in the event of another sudden bombing; the plans outlined are still being kept as a practical working basis.

WHAT WE HAD NOT PLANNED

It is hard to anticipate every eventuality ahead of time, and we found here that unexpected circumstances presented themselves, demanding solution. To mention a few:

1. The immediate and continued blackouts made night traveling difficult, slow and hazardous. Pregnant women who were developing symptoms of beginning labor were advised to get in touch with their physicians before nightfall and to enter the hospital during daylight hours as often as circumstances warranted. The radio and the press were used to disseminate such information.
2. The declaration of sudden martial law prohibited any one from being on the street at night except a few specially privileged classes. Police, taxicabs, doctors, civilian guards, aid station employees and ambulances were among the privileged classes. In the event of onset of labor at night, taxicabs and police patrol cars proved adequate for such transportation and the police radio patrol system proved efficient in locating the call of the pregnant woman with the minimum of delay.
3. A high percentage of our midwives proved to be aliens and were given no leeway in privileges of being on the street at night. They were quickly convinced that any of their patients going into labor at night would have to be referred to the nearest hospital as the only solution of that problem.
4. There was an abrupt increase in incidence of eclamptogenic toxemia. This is understandable when one realizes that a prolonged period of stress would tend to disrupt metabolism and throw a considerable extra load on the nervous system.
5. The question arose what to do with the early pregnant woman whose husband had suddenly been killed. There were numerous instances of women who had been severely shocked by the sudden loss of the husband in the unexpected catastrophe, added to which was the discovery of an early pregnancy. It was gratifying to note the renewed courage of each of these women when she was advised to carry through with her pregnancy for two logical reasons: (1) she would be able to have a living memory of her husband who died so gallantly and (2) she would be able to make a real contribution to the national program by bearing a child. I saw no hint of refusal to carry through after these facts had been carefully explained.

COMMENT

The experiences of managing a community wide obstetric program in Hawaii before, during and after a sudden major disaster are described in the hope that these facts may be of some value to other communities in their efforts to make similar plans. Previously made plans proved workable in an acute crisis, although several unanticipated problems arose which were solved without difficulty.

LATER.—Since the foregoing was written, Honolulu has had two air raid alarms and one bombing; the program outlined is still proving itself useful.

386 Young Hotel Building.

THE VENOGRAPHIC DIAGNOSIS OF
THROMBOPHLEBITIS OF THE
LOWER EXTREMITIES

ARNOLD STARR, M.D.

HOWARD A. FRANK, M.D.

AND

JACOB FINE, M.D.

BOSTON

Convincing evidence is rapidly accumulating that most pulmonary emboli of extracardiac origin arise from thrombophlebitis in the deep veins of the lower extremities.¹ The passage of an embolus from the leg to the lung can be prevented by division of the femoral vein. Indeed, Fine and Sears² have recently urged this procedure in all cases of deep thrombophlebitis of the lower extremity as the most effective prophylaxis against embolism. The prevention of pulmonary embolism depends on the early recognition of the venous thrombosis, but the clinical evidence of phlebitis may be equivocal or entirely lacking until a pulmonary infarct indicates its presence. A method which can establish the diagnosis and locate the side on which the process lies has been provided by the venographic technic recently described by Bauer.³ The benefits of this diagnostic procedure are the subject of this communication.

TECHNIC

The patient lies on his back with a 6 cm. block heel. A 14 by 17 inch x-ray film⁴ is placed under the leg, its lower edge about 3 inches above the ankle. A small incision is made about 1 cm. behind the external malleolus. A constant small vein is found here which communicates readily with the deep system. Through a fine needle 20 cc. of 35 per cent diodrast^{5a} is injected at a uniform rate during a period of sixty seconds. At the end of the injection the exposure is made.

Resistance to the injection may be notably increased over that encountered in the absence of deep thrombosis. A useful hint of the presence of thrombosis is a decid-

edly increased caliber of the vein at the ankle. If the foot is held in moderate inversion the shadow of the veins will not be obscured by that of the bones of the leg. The normal venogram shows the deep veins of the calf, the popliteal and the femoral vein well outlined. A few superficial veins also are seen. Thrombophlebitis is characterized by partial or complete absence of filling of the deep veins with the contrast medium. Superficial collateral channels may be evident even in the acute stage, although they are more obvious in long standing deep thrombophlebitis. When the venogram of an extremity is repeated, the identical pattern of normal filling or of a filling defect is reproduced.

The value of this type of venography is illustrated in the following cases:

CASE 1.—A woman aged 35 entered the hospital complaining of recurrent attacks of upper abdominal pain of several years' duration. A Graham test was positive for cholelithiasis. Cholecystectomy and choledochostomy were done. The post-operative course was uneventful except for an unexplained daily

Fig. 1 (case 1).—Normal filling of deep system on both sides.

low grade elevation of temperature during the second week after operation. The leukocyte count varied between 12,000 and 15,000. Because of these signs deep phlebitis in the legs was suspected and looked for, but no evidence for this diagnosis could be found. Venograms were done on both lower extremities during this period and normal findings were obtained (fig. 1). On the nineteenth postoperative day the patient complained of pain in the left calf and pain in the right side of the chest. Examination disclosed tenderness in the left calf and dulness to percussion and rales at the right lung base. Bilateral venograms were repeated and showed failure of filling of the deep veins of the left leg (fig. 2). Division of the left common femoral vein was done. At operation, six hours after venography, diodrast was found in the femoral vein. No clot or thrombus was present at the site of division. Within twenty-four hours the pain and tenderness in the left leg disappeared completely. Three days later the patient was allowed to be up and about and was discharged a week after division of the femoral vein free from all symptoms and signs in the chest and extremities. There was no edema in either leg.

In this case the unexplained low grade fever aroused the suspicion of deep phlebitis, but in the absence of evidence to support this diagnosis the first venograms were taken and found normal. When these were

repeated a week later following the appearance of pain in the leg and chest, a distinct change in the veins in the left leg was observed.

CASE 2.—A man aged 60 entered the hospital for the repair of a recurrent inguinal hernia. Examination disclosed hypertension, pulmonary emphysema and a right inguinal hernia. Herniorrhaphy was done, using fascia taken from the right thigh. The postoperative course was uneventful for twelve days. He was then allowed up in a chair. That evening he complained of pain in the left calf, which was found to be slightly tender on deep palpation. There was slight pain on dorsiflexion of the foot. There was no edema, cyanosis or increased heat. There was no elevation of temperature or pulse rate, and the leukocyte count was 10,700. A venogram of the left leg showed failure of filling of the deep system of veins (fig. 3). A venogram of the right leg taken for comparison showed normal filling of the deep veins. The small vein at the ankle on the left side was observed to have twice the diameter of the same vein on the right side, and there

Fig. 2 (case 1).—Second venogram of left leg showing acute thrombophlebitis with complete absence of filling of the deep veins of the lower leg, the popliteal vein and the lower part of the femoral vein. The greater and lesser saphenous veins are filled.

Fig. 3 (case 2).—Failure of filling of the deep veins below the popliteal is shown on the left. The superficial veins are larger and more numerous on this side.

was much more resistance to injection on the left side. The next morning the patient complained of a sudden onset of pain in the right side of the chest aggravated by inspiration. Rales, which were not present previously, were heard in the right lower lobe. A diagnosis of pulmonary infarction was made

and confirmed by a roentgenogram. Under local anesthesia the left femoral vein was divided just distal to the profunda femoris. The vein at this level appeared normal, but when it was divided diodrast escaped from its lumen. This was interpreted as being due to a greatly retarded blood flow from the veins blocked by thrombus. The patient became free from pain and tenderness in the leg within twenty-four hours after division of the vein. Later there was a small pleural effusion and evidence of infection in the infarcted area of the lung. Further progress was satisfactory until the twenty-third post-operative day, when after having been up and around he experienced severe pain in the left side of the chest followed by hemoptysis. Severe dyspnea and cyanosis developed. Examination showed rales and a friction rub in the left lower part of the chest and evidence of infarction in the left lower lobe, which was confirmed by roentgenography. Since the source of the second infarct was uncertain, venograms were again taken of both legs. The injection on the left side was made into the great saphenous vein in the mid thigh, as suggested by Bauer, in order to outline the femoral vein proximal to the site of division as well as the iliac vein. The roentgenogram (fig. 4) showed normal filling of these structures. The venogram on the right side, however, disclosed an absence of filling in one of the tibial veins, and this was considered to be due to thrombosis (fig. 5). Accordingly, despite the patient's respiratory distress the right femoral vein was divided below the vena profunda under local anesthesia. Although convalescence from the pulmonary complication was somewhat stormy for a few days, recovery followed.

If left femoral vein ligation in this case had been done immediately after the venogram disclosed evidence of thrombosis, the first infarction might have been averted. When the second infarct occurred, further venography excluded thrombosis in the left common femoral and iliac veins and located the block in the right anterior tibial vein.

CASE 3.—A man aged 38 entered the hospital complaining of pain in the right side of the chest and cough of three weeks' duration. The history disclosed that asymptomatic varicose saphenous veins had been present for ten years in the right leg. These had been injected five years before admission. Physical examination was negative except for dullness and diminished breath sounds throughout the lower two thirds of the right lung field and varicosities of the saphenous system of the right leg. Roentgenograms of the chest showed a pleural effusion. Thoracentesis yielded grossly bloody fluid. Culture, Gram and Ziehl-Neelsen stains showed no bacteria. No tumor cells were found in the sediment of the centrifuged pleural exudate. Pulmonary infarction was considered in the differential diagnosis. Accordingly, the deep veins of the legs were investigated. No clinical evidence of deep phlebitis was apparent, but venography showed failure of filling of the deep system on the right side (fig. 6). The venogram of the left leg

Fig. 4 (case 2).—Venogram of left common femoral vein and iliac vein. This roentgenogram was taken after the injection of diodrast into the greater saphenous vein in the thigh, ten days after division of the femoral vein below the profunda. No evidence of disease of the veins is present.

showed normal deep veins. The right common femoral vein was divided. No clot was found at the site of division, but diodrast escaped from the distal end of the divided vein as in the previous cases. The convalescence was uncomplicated. The pleural effusion gradually disappeared. Further x-ray studies disclosed no evidence of disease in the pulmonary parenchyma. The patient was discharged eight days after operation with no edema or disability in the legs.

In this case the only symptoms were pain in the chest and cough. The only significant physical findings were the superficial varicosities of the right leg and a bloody pleural effusion. Neoplasm, tuberculosis and the presence of pulmonary infarction were considered in the differential diagnosis. Despite complete absence of clinical evidence of phlebitis, venographic investigation of the legs gave clear evidence of an obstructive process in the deep veins of the right leg (fig. 6). The right femoral vein was divided to prevent the occurrence of further pulmonary infarction.

CASE 4.—A woman aged 40 entered the hospital complaining of urinary incontinence. She was obese and had hypertension. Two vaginal operations for incontinence were done in a period of two months. At the end of this time, when the patient was allowed out of bed, she complained of difficulty in walking because of pain in both calves, which were tender on pressure. A daily temperature elevation of 1 degree was noted, but there was also evidence of mild urinary sepsis. It was not clear whether or not the patient had deep phlebitis. Venograms showed normal filling of the deep veins of the legs (fig. 7). The patient was therefore allowed to continue to walk about, with gradual disappearance of the discomfort in the legs.

This patient's complaint of pain in the legs when first allowed out of bed and the low grade temperature elevation suggested the possibility of bilateral phlebitis, but the normal venograms provided the only assurance obtainable that she could be permitted to be active without fear of a pulmonary embolus.

COMMENT

Until recently venography has been unsatisfactory for the diagnosis of thrombophlebitis because the techniques utilized were incapable of visualizing the entire deep system of veins. Since evidence is now available¹ that the source of most pulmonary emboli is thrombophlebitis in the deep veins of the lower leg, the venographic method of Bauer, which adequately visualizes

Fig. 5 (case 2).—Second venogram of right leg. The failure to outline the greater part of the anterior tibial vein by this venogram in contrast to the better filling shown by the previous venogram of the same leg (fig. 3) suggests the development of thrombosis in this vessel.

these veins,⁵ provides the most reliable means of establishing the diagnosis when the signs and symptoms are inconclusive or wholly lacking. An extremely useful guide for the institution of prophylactic therapy for pulmonary embolism is thus provided.

The possibility of setting up thrombosis in the veins by injection of diodrast is probably not an important consideration in view of Bauer's experience and the absence of phlebitis following the use of diodrast for intravenous urography. A long exposure (twenty-four hours in one instance) of the intima of the femoral vein to diodrast has been observed without gross evidence of injury.

Phlebitis has not developed at the site of injection, even when it is repeatedly done. We have nevertheless adopted the suggestion of Dougherty and Homans⁶ that the vein be washed out with saline solution after the injection of the diodrast. Another theoretical hazard, i. e. the release of a clot by the pressure of the injected fluid, has not occurred to our knowledge.

We have observed dilatation of the constant small vein at the ankle which is used for the injection in the presence of thrombophlebitis. We have also noticed increased resistance to the injection in the presence of thrombophlebitis.

The finding of diodrast in the femoral vein at the time of division is evidence of a retarded flow in the deep system of veins and provides indirect confirmation of the venographic diagnosis of thrombophlebitis.

There is frequently good reason for performing venography on both sides, not only to confirm or refute the clinical evidence on the side under suspicion, but also to demonstrate the presence or absence of the disease in the unsuspected side. It should be clear that

and our experience to date suggest that, when properly performed, a normal venogram can be regarded as conclusive evidence against thrombophlebitis in the veins visualized.

After operation patients commonly experience pain in the calves when they first begin to walk. In this situa-

Fig. 7 (case 4).—The deep veins fill normally.

tion a suspicion of phlebitis with its implied danger of embolism is unavoidable. Heretofore a guide to an intelligent choice of action has not been available. Fatal embolus just before or soon after discharge from the hospital occasionally results in such circumstances. By utilizing the venographic method under discussion a means of instituting preventive therapy is now possible.

CONCLUSIONS

1. A technic described by Bauer for the visualization of the deep veins of the leg has been useful in the diagnosis of acute thrombophlebitis.

2. The early diagnosis of thrombophlebitis by this method facilitates the institution of effective prophylaxis against pulmonary embolism at an earlier period than has been possible heretofore.

520 Beacon Street.

Fig. 6 (case 3).—The deep veins of the upper half of the right lower leg, the right popliteal vein and the right femoral vein do not fill. The venous return is by way of the varicose external saphenous vein.

the process is frequently bilateral and that an embolus may arise from either side whether or not signs and symptoms are present. The data provided by Bauer

5. The method advocated by Dougherty and Homans⁶ is substantially the same as that advocated by Bauer, although the former authors applied the method primarily for study of the veins in the thigh rather than the lower leg. Bauer emphasized the value of roentgenographic evidence in the lower leg for the diagnosis of acute thrombophlebitis. A 14 by 36 inch film and cassette is now available for filming the entire leg.

Leadership.—If four men guess wrongly on a given prediction and the fifth man guesses rightly we say "how wise" when in reality we ought to say "how lucky." A guess that turns out right is not a prediction; it remains a guess. A man whose prediction is justified by future events need not necessarily have found the one solution possible. In much of science there is one answer and one answer only to a given problem. It is not plus or minus four but plus four and not minus four. In many social problems, on the other hand, the correct solution is the acceptable solution, the workable solution, and there may be several such solutions. Lincoln found his solutions by a method all his own. He himself disclaimed leadership. He said the people led. He waited until he thought that he knew what the people were thinking. There is another type of leadership that may be higher still, the type that teaches a people to understand what it ought to want. Only in conversation, using the term in its broadest sense, has this been done in American life, with conspicuous failures all too often in oil conservation, soil conservation, forest conservation.—Bowman, Isaiah: Enduring Purpose, *Assn. Am. Coll. Bull.* 26:194 (May) 1940.

PROPERTY OF THE
HOUSE COMMITTEE

CHRONIC HEMOLYTIC STREPTOCOCCUS ULCERS OF THE EXTREMITIES

FREDERIC W. TAYLOR, M.D.

INDIANAPOLIS

It is indeed strange that chronic hemolytic streptococcus ulcers of the extremities have received so little attention and comment. This is all the more unusual since the lesion itself forms a clearcut entity and since there is a specific treatment for the condition.

There are but 5 of these cases reported in recent literature.¹ Nevertheless, 31 such cases were seen in the surgery clinic of the Indianapolis City Hospital during the past two and one-half years. The inference is obvious. Many chronic hemolytic streptococcus ulcers of the extremities have gone undiagnosed. In fact, none were found at the Indianapolis City Hospital until Goodman's¹ report in 1938.

DESCRIPTION

Since so many streptococcic ulcerations have recently been described, it is essential that a clearcut picture be

Practically all the ulcers are found on the lower leg. In the present report only two were present on the hand.

The hemolytic streptococcus can be found in cultures from all ulcers, although it may not be identified on the first culture. This organism may appear in pure culture but most frequently has some contaminant. In the present report the contaminant was *Staphylococcus albus* in one half of the cases. These contaminating organisms are not considered to be growing in symbiosis with the hemolytic streptococcus.

There is one feature of the disease which is of considerable aid in suggesting the diagnosis. Most chronic ulcers have a definite background. They are superimposed on old varicosities, arteriosclerosis, frost bite or syphilis. This is not the case in chronic hemolytic streptococcus ulcer. This ulcer has no such background. It appears usually where there is no vascular impairment and where the circulation is quite adequate. It is seen most frequently in children and young adults. The average age at the Indianapolis City Hospital was 22.7 years. The oldest patient was 57, the youngest 3

Fig. 1 (H. B., aged 40) —Ulcer and excoriation over anterior tibial region spreading under local treatment. This followed a bruise and slight abrasion two months prior to A. B, after eighteen days of sulfanilamide 60 grains (4 Gm.) daily. C, complete healing after dropping off of crust a few days later.

given of the condition at hand. It bears no relation in appearance or course to the burrowing ulcers or symbiotic gangrene described by Meleney.²

The ulcer starts at the site of a slight cutaneous excoriation or insect bite. After a few days a small indolent ulcer appears. This is usually about 1 cm. in diameter but may progress slowly to 5 or 6 cm. in a week or two. Pain is not an outstanding feature.

The ulcer has none of the characteristics which suggest to the clinician the possibility of a hemolytic streptococcus infection. The tissue reaction is slight, being confined to the reddened ulcer margin. This may or may not be undermined. There is no surrounding edema or lymphangitis. The base of the ulcer weeps a watery serum from a pale atrophic granulation tissue. The lesion as a whole gives the impression that the tissues are making little or no effort to heal the defect.

CASES

The cases identified and studied were seen in the outpatient surgical clinic of the Indianapolis City Hospital. No attempt has been made to list the cases separately. They have been summarized and the results noted. Three typical cases are shown in the accompanying illustrations. All cases were seen during the two and one-half year period starting in October 1938 and ending in April 1941.

During this time 52 chronic ulcers were studied. From these were obtained one or more cultures of the (beta) hemolytic streptococcus. Of this number there were 21 ulcers which were considered to have a definite background of vascular impairment or syphilis. These were dropped from the present study, leaving 31 cases in which the ulcer was thought to be due primarily to the hemolytic streptococcus. No other contributing cause could be found.

All ulcers appeared on the lower extremity with two exceptions. These were in children with several ulcers over the dorsum of the hand and arm. There were 2 instances in which more than 1 member of the same family had a chronic hemolytic ulcer at the same time.

S. and Friedman, Reuben: Chronic Streptococcal Ulcer of the Skin Responding to Sulfanilamide, *Arch. Dermat. & Syph.* 29:554 (March) 1939. Hamburger, H. J.: Observations on the Pathology and Therapy of the So-Called Frontier Sore, *Indian M. Gaz.* 74:151 (March) 1939.
2. Meleney, F. L.: Zinc Peroxide in the Treatment of Microaerophilic and Anaerobic Infections, *Ann. Surg.* 101:997 (April) 1935.

Two patients were admitted to the hospital for treatment. The rest were handled entirely as outpatients. All cases were followed, and so far there have been no recurrences in the primary hemolytic streptococcus ulcer group.

The ulcers varied in size from 1 cm. to 6 cm. Local adjacent skin inflammation or edema was found in only 5 instances. The remaining cases merely showed an indolent sluggish ulcer with little or no reaction.

The patients had had their lesions for from two weeks to four years when specific therapy was started in the hospital. Omitting the four year case, the average duration of the ulcer was two months. During this time they had received all types of home remedies plus those used currently in the clinic. The use of the latter drugs depended on the whim of the particular clinician. They included 2 per cent methylosaniline (gentian violet), tincture of merthiolate, scarlet red ointment, boric acid ointment, zinc oxide ointment, ammoniated

were not followed on all the patients, but this is a precaution which certainly should not be overlooked.

Occasional blood sulfanilamide determinations were made. These were rather low, varying from 3.5 to 5.2 mg. per hundred cubic centimeters of blood. Apparently no greater concentration was necessary in this type of infection.

RESULTS

There were 5 of the 31 cases of primary chronic hemolytic streptococcus ulcer which healed under local wet dressings and applications. These healed in an average of fourteen days.

Six more patients received entirely inadequate amounts of sulfanilamide. Several of these were lost temporarily to the clinic and continued with local home remedies. Their ulcers eventually all closed in an average of fifty-one days.

This leaves 19 patients who received adequate amounts of sulfanilamide. These patients had had their

Fig. 2 (W. Y., Negro aged 26 years).—A, ulcers present for four years and being treated regularly in the surgical clinic. When cultures were finally taken and hemolytic streptococci found, 10 ulcers were present. B, after two days of sulfanilamide, ulcers showed signs of healing with healthy granulations. C, ulcers completely healed after fourteen days of sulfanilamide 60 grains (4 Gm.) daily.

mercury ointment, wet dressings of physiologic solution of sodium chloride, magnesium sulfate, Burow's solution, diluted solution of sodium hypochlorite, 70 per cent alcohol and dusting powders of thymol iodide and sulfanilamide.

TREATMENT

The lesion usually received varying amounts of the foregoing drugs. Then some one usually became curious as to why healing did not take place and finally took a culture. When a positive culture was obtained, specific therapy was instituted.

Specific therapy consisted of oral sulfanilamide as suggested by Goodman.¹ The adult dosage varied from 20 to 90 grains (1.3 to 6 Gm.) daily. In general the smaller doses were ineffectual but doses of from 60 to 70 grains (4 to 4.5 Gm.) daily seemed quite sufficient.

The patients were followed in the outpatient clinic to guard against untoward reactions. Blood counts

ulcers for from two weeks to four years. Omitting the case of four years' duration, they had had their ulcers for an average of seven and seven-tenths weeks. Following the specific drug therapy the ulcers were healed in an average of one and eight-tenths weeks.

The dramatic rapidity with which some of these chronic ulcerations heal is nicely shown in figure 2. The ulcerations had been present in this 26 year old Negro for four years. During most of that time he had been seen in the surgical clinic several times a week. During that time he had received every type of ointment and solution on the dressing table. At the time the condition was finally recognized, he had 10 ulcers measuring from 1 to 2 cm. in diameter. He was given 60 grains (4 Gm.) of sulfanilamide daily for fourteen days. At the end of this period the ulcers were completely healed for the first time in four years. They have remained healed.

The rapidity of healing under specific therapy is one of the most striking features of these ulcers. It is indeed thrilling to see them literally heal before one's eyes.

What has been said about the specificity of sulfanilamide holds true only for primary chronic hemolytic streptococcus ulcers and not for all chronic ulcers which contain this organism. During the course of the present study 21 ulcers were encountered which contained hemolytic streptococci but had as their basis varicosities, phlebitis, arteriosclerosis or syphilis. These patients were given sulfanilamide. The result was a disappearance of the hemolytic streptococcus, but the fundamental background of the ulcer still persisted and so did the ulcer.

One of the cases which was considered clinically and bacteriologically to be typical of chronic hemolytic streptococcus ulcer failed completely with sulfanilamide. Under this therapy the hemolytic streptococcus disappeared but the ulcer persisted. No other background

improvement. The suggestion is therefore made that, in vascular ulcers containing hemolytic streptococci, sulfanilamide be used as an adjunct to other forms of therapy. The drug, of course, would be useless when the organism is not present.

An interesting feature in epidemiology is noted in this Indianapolis City Hospital series. Of the 31 cases of primary chronic hemolytic streptococcus ulcer 27 (87 per cent) had their onset in the last six months of the year. This does not mean that this number were all treated during this period but that 87 per cent started from a scratch, abrasion or insect bite which was received between the first of June and the last of December. No adequate explanation has been found for this seasonal incidence. The contagious nature of the lesion is indicated by the fact that five ulcers occurred in two families. Three members of one family had ulcers at the same time, as did two in a second family.

In the cases here reported sulfanilamide was given orally. It is interesting to speculate on the possibility

of applying the powdered drug directly on the local wound. It would seem to be an ideal situation for such use. The truth is that the oral use has been so completely satisfactory and specific that those in charge were loath to make the change. The drug was used locally in treatment of 1 patient with a vascular background caused by previous trauma. The ulcer was over the right anterior tibial region and measured 4 cm. in diameter. It had been present for one and one-half years. From the wound the specific organism was cultured and the patient started on sulfanilamide. This proved too toxic to him and so the powdered drug was applied locally. The hemolytic streptococcus had disappeared from the wound when cultures were taken three weeks later and the ulcer was completely healed at forty days (fig. 3). It is planned to use powdered sulfanilamide locally in subsequent cases of primary chronic hemolytic streptococcus ulcer.

Fig. 3 (M. R., aged 41) —A, chronic ulcer of anterior tibial region containing hemolytic streptococci. Duration, one and one half years. The ulcer had a vascular background following an injury. The patient could not tolerate oral sulfanilamide and so the powder was applied locally. Hemolytic streptococci had disappeared from the wound when a culture was taken three weeks later. B, complete healing after forty days of powdered sulfanilamide locally and no other type of therapy.

could be found in this patient. The ulcer finally healed on home remedies one month after the patient left the hospital. It is possible that a fungous infection was an added factor here, though laboratory findings are lacking. Nevertheless this case represents a flat failure, since it answered all the requirements of the chronic hemolytic streptococcus ulcer.

COMMENT

It must be emphasized that chronic hemolytic streptococcus ulcer is a very distinct entity and one which is rather frequently encountered. The oral use of sulfanilamide is specific for the lesion. This is true with the exception of an occasional case which is either resistant or more probably misdiagnosed. Among the present series there was 1 such case in 19 in which adequate doses of sulfanilamide were administered. Healing in the remaining cases was spectacular.

The hemolytic streptococcus was also cultured from a large group of varicose and other vascular ulcers. Of course, in these instances sulfanilamide did not cure the lesion. It did, however, cause considerable

SUMMARY

1. Chronic hemolytic streptococcus ulcers of the extremities constitute a definite entity with a specific therapy.

2. The lesion is characterized by its chronicity, similarity to chronic ulcers having vascular backgrounds, and lack of inflammatory reaction which might suggest its true nature. Usually it is seen in children and young adults with no vascular impairment. Diagnosis is confirmed by the culture of hemolytic streptococci from the ulcer. In no way does it resemble the symbiotic burrowing streptococcus ulcers.

3. Only 5 chronic hemolytic streptococcus ulcers have been reported in recent literature. None were seen at the Indianapolis City Hospital until a search was made for them. Thirty-one such cases were seen and treated in this institution in the past two and one-half years. The deduction is obvious.

4. This type of ulcer may heal under local treatment. Usually it does not. Oral sulfanilamide is specific.

5. There were 19 cases in the present series in which adequate amounts of sulfanilamide were given. These ulcers healed completely in an average of one and eight-tenths weeks, although they had first been treated locally with all types of drugs for an average of seven and seven-tenths weeks.

6. The local use of powdered sulfanilamide would seem to be indicated in this type of lesion, though it was not used in the present series.

7. It is suggested that cultures be taken of all chronic ulcers of the extremities to identify those belonging to the chronic hemolytic streptococcus group. In chronic ulcer cases with a vascular background and containing hemolytic streptococci, sulfanilamide might well be employed as an adjunct to other forms of therapy.

OBSERVATIONS ON THE "EGG WHITE INJURY" IN MAN

AND ITS CURE WITH A BIOTIN CONCENTRATE

V. P. SYDENSTRICKER, M.D.

S. A. SINGAL, Ph.D.; A. P. BRIGGS, M.D.

N. M. DEVAUGHN, M.D.

AUGUSTA, GA.

AND

HARRIS ISBELL, M.D.

BETHESDA, MD.

Many investigators have noted that the inclusion of large amounts of egg white in special experimental diets causes a definite nutritional disease in animals. This disorder, commonly called egg white injury, has for its chief symptom an "eczematous dermatitis" which can be prevented or cured by a protective substance formerly called vitamin H which is present in certain foodstuffs. There appears frequently in rats, in addition to the severe general eczematous dermatitis involving the eyelids and lips, an ischemic gangrene of the tip of the tail, presumably due to local vasoconstriction. Recent reports¹ have indicated that vitamin H is identical with biotin, a yeast growth factor, and also with coenzyme R, a growth and respiration factor for many strains of the legume nodule organism *Rizobium*. Williams and his co-workers² have demonstrated that the so-called egg white injury is due to an induced biotin deficiency caused by the binding of the dietary biotin by a protein fraction of raw egg white "avidin," thereby preventing the absorption of this vitamin from the intestinal tract.

In chicks a scaly dermatitis not due to pantothenic acid deficiency has been cured by vitamin H concentrates,³ while biotin concentrates have protected turkey poult against a specific dermatitis.⁴ It appears that

this vitamin is also involved in the graying of fur in rats and mice⁵ as well as in the synthesis of lipids by the rat.⁶

In view of the growing significance of biotin in animal nutrition, it seemed important to determine whether any of the phenomena of human deficiency disease might be related to biotin deficiency. To this end a small group of volunteers ate a diet planned to contain a minimal amount of biotin, which was composed of rice 125 Gm., patent white flour 80 Gm., farina 75 Gm., cane sugar 205 Gm., lard 32 Gm., washed butter 10 Gm. and lean beef 25 Gm. To this was added 200 Gm. of dehydrated egg white. The basal components represented 387 Gm. of carbohydrate, 31 Gm. of protein and 32 Gm. of fat, with a total caloric value of 1,960. In addition, 928 calories was derived from the 160 Gm. of protein and 32 Gm. of fat of the egg white for a grand total caloric value of 2,888. As the egg white was given in solution in a one-third aliquot with each meal, the percentage of egg white of the total food ingested daily was dependent on the amounts of the other components consumed. Usually the egg white furnished in excess of 30 per cent of the total daily caloric intake. Such a diet is poor in vitamins of the B complex except for riboflavin, which is present in desiccated egg white in amounts approximating 10 mg. per hundred grams.⁷ Consequently the following vitamin supplement was given daily: thiamine hydrochloride 6 mg., riboflavin 9 mg., nicotinic acid 75 mg., pyridoxine 5 mg. and calcium pantothenate 5 mg. In addition, ascorbic acid 75 mg., vitamin A 5,000 units, ferrous sulfate 1 Gm. and calcium lactate 1 Gm. were given.

Of seven volunteers, it has been possible to continue 4 under observation to a satisfactory conclusion. Three were white men, the fourth a Negro woman. All were in good general condition and free from symptoms and

Excretion of patient J: shaded area, biotin excretion; unshaded area, biotin administered.

signs of avitaminosis when the experiment was begun. During the third and fourth weeks all 4 subjects developed a fine, scaly dermatitis which did not itch and

The authors were given constant help and valuable suggestions by Dr. R. E. Butler and technical assistance by Mrs. Marjorie Bie.

This investigation was made possible by grants in aid by the John and Mary R. Markle Foundation and an anonymous donor, and by donations of vitamins by many manufacturers.

7. Personal communication to the authors from Armour & Co., Chicago.

which disappeared spontaneously. Thereafter nothing of significance was noted until the seventh week, when 1 patient developed a maculosquamous dermatitis of the hands, arms and legs. During the seventh and eighth weeks all patients showed a striking grayish pallor of the skin which was out of proportion to the blood picture and was interpreted as evidence of peripheral vasoconstriction. During the same period the 3 white patients showed definite atrophy of the lingual papillae, patchy with the production of a "geographic" tongue in 1, general in 1 and affecting the lateral thirds of the tongue in the third. The Negro patient showed no tongue changes until the fourteenth week of the experiment, when rather rapid denudation of the tongue began. It was notable that the tongues of these patients remained pale with none of the capillary engorgement seen in pellagra or ariboflavinosis. During the ninth and tenth weeks all patients showed dryness of the skin of the extremities with well defined reticulation and a tendency again to fine, branny desquamation; this dermatosis was very similar to that observed during the early period of the experiment. No ocular or genital lesions were observed.

After the fifth week prominent symptoms were strikingly similar to those reported for experimental thiamine deficiency. Mild depression progressed to extreme lassitude, somnolence, hallucination in 1 patient and a mild panic state in 2. Muscle pains, hyperesthesia without demonstrable neurologic changes and localized paresthesias occurred in all 4 subjects. No definite reflex changes were observed. Anorexia progressed to nausea and sitophobia. It was extremely difficult to get these subjects to continue the diet. The caloric intake fell off rapidly in all during the last three weeks of the experiment. Two patients with electrocardiographic evidence of coronary ischemia had precordial pain. The electrocardiograms could not be differentiated from those attributed to thiamine deficiency.

Examinations of the blood at weekly intervals showed a definite diminution in the hemoglobin content, the number of erythrocytes and particularly the volume of packed red cells. These changes occurred in spite of a theoretically adequate intake of iron and a very large protein fraction in the diet. All 4 patients showed an increase in bile pigments and cholesterol in the blood.

Determination of biotin excretion in the urine showed that at the end of seven and eight weeks of the experimental regimen the subjects excreted from 3.5 to 7.3 micrograms of biotin in twenty-four hours as compared with the excretion of 29 to 62 micrograms by persons taking a normal diet.⁸

Treatment with an injectable biotin concentrate⁹ has been completed in 3 of the 4 experimental subjects. The daily dose has varied from 75 to 300 micrograms. The minimal amount required for prompt relief of symptoms seemed to be 150 micrograms daily. Depression, muscle pain, precordial distress and anorexia have been abolished on the third to fifth day of treatment. Striking relief of depression amounting almost to euphoria occurred in 2 patients. Active distaste for the diet was replaced by willingness, even eagerness, to eat it although there was no significant increase in the amount consumed. The striking ashy pallor disappeared in four days. Insufficient time has elapsed for evaluation of other evidences of correction of physiologic disturbances.

Immediately after the administration of 150 micrograms of biotin concentrate the urinary excretion rose rapidly from a deficiency level of 3 to 7 micrograms a day to a level approximating 55 micrograms. This level was maintained until the dose was increased to 300 micrograms a day, when there was a further step-wise increase in biotin excretion to a level approximating 140 to 150 micrograms daily with an immediate fall to a level slightly lower than those found in patients eating a normal diet when medication was discontinued. The excretion chart of patient 3 is typical of the patients observed.

SUMMARY AND CONCLUSIONS

In observations on human subjects maintained on a diet very poor in all vitamins of the B group except riboflavin supplied by egg white, supplemented with adequate amounts of available synthetic vitamins, in which at least 30 per cent of the total calories were supplied by desiccated egg white, definite symptoms and signs were produced.

Symptoms and signs were rapidly cured by the parenteral administration of a biotin concentrate in doses representing 150 to 300 micrograms of biotin per diem.

The phenomena observed were similar to some of those seen in spontaneous avitaminoses.

AGNOGENIC MYELOID METAPLASIA OF THE SPLEEN

REPORT OF FIVE CASES ILLUSTRATING DIAGNOSTIC DIFFICULTIES AND THE DANGER OF SPLE- NECTOMY AND RADIATION THERAPY

CARL REICH, M.D.

Associate in Medicine, Lenox Hill Hospital; Hematologist, Hospital
for Joint Diseases, and Associate Physician, City Hospital

AND

WILLIAM RUMSEY JR., M.D.

House Physician, Lenox Hill Hospital

NEW YORK

The clinical picture of splenic enlargement with anemia has always been of great interest to the internist, the surgeon and the pathologist. This syndrome is observed from infancy up to old age and is associated with many different conditions, most of which are little understood although they are characterized by definite names. Thus we have only to enumerate such names as erythroblastosis fetalis, Cooley's anemia, chronic sub-leukemic myelogenous leukemia, splenic anemia and Hodgkin's disease. Each one brings to mind a rather definite clinical and pathologic picture, and yet there are many so-called atypical cases in which the disease defies classification both during life and after death of the patient.

In a recent report Jackson, Parker and Lemon¹ integrated as a clinical entity a syndrome characterized by splenic enlargement and the presence of immature red and white cells in the blood. This condition is often erroneously diagnosed as chronic myelogenous leukemia, splenic anemia, erythroblastosis or Hodgkin's disease. Frequently the picture is so confusing that a splenectomy is performed, with unfavorable results.

It is our purpose in this communication to cite briefly 5 additional cases of this disorder and to point out the diagnostic errors, both clinical and pathologic, which were made until the picture was finally clarified.

8. Biotin determinations were done by Dr. Isbell of the National Institute of Health.

9. Biotin concentrate was supplied by the S. M. A. Corporation, Chagrin Falls, Ohio

1. Jackson, Henry, Jr.; Parker, Frederic, Jr., and Lemon, H. M. *New England J. Med.* 222:985 (June 13) 1949

As a final check, our clinical and pathologic material was passed on by Jackson and Parker; so we are sure that we are dealing with the condition described by them.

REPORT OF CASES

CASE 1.—Y. J., a white man aged 52, an electrician, first admitted to the hospital on Jan. 14, 1935, had had ten teeth extracted six months prior to admission and afterward had noticed shortness of breath on mild exertion, generalized weakness and night sweats. The sweats were constant, occurring one or two hours after midnight every night. The weakness had become more severe during the last two months.

His past history included gonorrhea twenty years and a fracture of the ankle twenty-two years before admission; otherwise his general health had been good. The family history was irrelevant.

Physical examination showed that he was well developed and nourished but appeared chronically ill. There was no icterus. The skin was of fair turgor and gave evidence of some loss of weight. It had a peculiar, waxy, light yellow tinge. The mucous membranes of the mouth were pale. The heart showed a soft systolic murmur at the apex which was not transmitted. The spleen was greatly enlarged, extending medially to the umbilicus and 4 fingerbreadths below the umbilical line on the left. No axillary, cervical or inguinal adenopathy was noted. The remainder of the physical examination was negative.

On January 17 examination of the blood showed hemoglobin 46 per cent, red blood cells 2,500,000, white blood cells 7,600, mature polymorphonuclear leukocytes 69 per cent, band cells 5 per cent, young forms 2 per cent, lymphocytes 5 per cent, monocytes 9 per cent, myelocytes 6 per cent, promonocytes 2 per cent, eosinophils 1 per cent, basophils 1 per cent, reticulocytes 5 per cent and platelets 150,000. There were severe poikilocytosis and anisocytosis, and many nucleated red blood cells were seen.

The following day a sternal puncture was done which gave no evidence of leukemic infiltration. A fragility test of the red cells showed that hemolysis began in a 0.425 per cent salt solution and ended in a 0.350 per cent salt solution. The Wassermann reaction was negative.

A roentgenogram of the chest showed a cardiac shadow large in all diameters. The lungs showed no evidence of tuberculosis or metastases. A flat film of the abdomen showed a shadow in the left upper quadrant and gave evidence of slight enlargement of the liver.

It was felt that the patient might benefit by splenectomy, provided the hemoglobin level could be raised preoperatively by transfusion, since the removal of such a large spleen would probably cause a great blood loss. Accordingly, the patient received three transfusions of 500 cc. of blood at three day intervals. After the last transfusion he had a reaction, the temperature rising to 104.2 F. Hemoglobinuria was not noted. The liver became somewhat enlarged during the ten days. The preoperative hemoglobin content was 60 per cent and the red cell count 3,200,000.

On February 7 splenectomy was performed with the patient under spinal anesthesia. The preoperative diagnosis was a tentative one of Banti's disease. The patient withstood the procedure well. The spleen weighed 2,850 Gm. The serosa of the spleen was free from adhesions. The surface was for the most part mottled red and reddish brown. There were also some irregular, scattered, dark purplish areas and a number of contracted, linear, yellow areas. The largest of these areas measured 2.2 by 0.4 cm. and on section showed irregular, yellowish, contracted tissue about which were some purplish petechiae. This tissue was firmer than the surrounding splenic substance. On the lateral surface was an irregular, orange red, slightly raised area 3.5 by 1 cm. Section through this area showed orange red tissue which extended in an irregular pattern down about 3.5 cm. and was firm, granular and shiny. Other sections of the cut surface were granular, shiny and reddish brown.

Microscopically the spleen showed typical myeloid metaplasia with numerous megakaryocytes and hemochromatosis.

The patient lived five years after splenectomy. In that time he had more than twenty separate hospital admissions and

received more than fifty blood transfusions. His complaints were always essentially the same: dyspnea, weakness and night sweats. The last year before death dependent edema developed, and he eventually died from cardiac failure and terminal endocarditis.

Autopsy showed advanced osteosclerosis of all bones, particularly the femur, tibia and skull cap. Microscopically there were no changes indicative of leukemia in liver, kidney or marrow. The lymph nodes showed extreme infiltration with megakaryocytes without leukemic changes. There were extramedullary areas of hemopoiesis in liver and lymph nodes. There was also evidence of hemosiderosis in the pancreas and liver. The heart was enlarged and showed evidence of myocardial degeneration.

CASE 2.—T. F., a Russian woman aged 44, a dressmaker, was first admitted to the hospital on Oct. 14, 1938. Eight years before an enlarged spleen had been discovered during a routine examination for a "nervous breakdown." At that time she was in another hospital for one week, where the diagnosis of myelogenous leukemia was made. She was followed by the outpatient department for a number of years. No roentgen therapy was given because of a persistently low white cell count.

Since that time she had felt an increasing weight and sense of pressure in the left side of the abdomen. She had lost about 6 pounds (2.7 Kg.) in the last eight years. For the past two years her appetite had been poor and she practically always felt nauseated. Two and a half months before admission she had had a bout of vomiting with diarrhea following the ingestion of soft shelled crabs. She was seen by her physician, who sent her to another hospital for a transfusion, after which she felt better. She entered Lenox Hill Hospital after this for further study.

Her past history included diphtheria at the age of 15, with no sequelae, and a progressive scoliosis first noted at the age of 12, for which she was put in a plaster cast without any curative result. Her last menstrual period had been at the age of 43, a year prior to admission. She had been pregnant twice, once ten years and once eight years before admission. Both pregnancies were terminated for pernicious vomiting. The remainder of her past history was not significant. The family history was noncontributory save that two sisters had had "thyroid trouble."

Physical examination showed that the patient was poorly developed but fairly well nourished. The skin and mucous membranes were pale. The thyroid was somewhat enlarged along the lower margin, with a firm strip of tissue across the neck. No palpable cervical glands were present. The heart and lungs were normal. The thorax was asymmetrical. The spine showed scoliosis to the right, with the maximum curvature at about the fifth thoracic vertebra. There was moderate lordosis of the thoracic portion of the spine, with flaring of the right scapula. The entire left side of the abdomen was occupied by a smooth, firm, ovoid mass extending from the costal margin to below the iliac crest and from the midaxillary line to 3 cm. beyond the midline. There was moderate tenderness in the epigastrium medial to the mass and in the right upper quadrant. The edge of the liver and the kidneys were not palpable.

The hemoglobin content was 75 per cent, the red blood cell count 3,600,000 and the white cell count 13,800, with the following differential count: mature polymorphonuclear leukocytes 42 per cent, band cells 11 per cent, young forms 14 per cent, lymphocytes 22 per cent, monocytes 8 per cent, eosinophils 2 per cent and basophils 1 per cent. The red cells showed anisocytosis, poikilocytosis and polychromasia. There were 2 normoblasts per hundred white cells. Another differential count five days later showed 13 per cent myelocytes, 5 per cent myeloblasts and 2.7 per cent reticulocytes. Hemolysis of the red cells began in a 0.375 per cent solution, showing an increased fragility.

Roentgen examination of the chest showed scoliosis, but no mediastinal lymph node enlargement was seen. Roentgenograms of the long bones showed no osteosclerosis.

Since the diagnosis was doubtful and the presenting complaint was the discomfort caused by the spleen, peritoneoscopy

and a splenic biopsy were performed. These ruled out the possibility of leukemia or Hodgkin's disease but did not result in a definite diagnosis. The pathologic diagnosis from the biopsy was "probable neoplasm of the spleen." Accordingly, the patient was given a transfusion of 500 cc. of whole blood preoperatively, and on November 14 splenectomy was done, followed by a postoperative transfusion of 300 cc. She did fairly well and was discharged two weeks after splenectomy.

The spleen weighed 1,800 Gm. The surface was firm, gray red and glistening. On section there was a slightly increased resistance to the knife. Scattered over the cut surface there were many slightly raised, fairly well circumscribed, yellow red nodules measuring 0.3 to 1.2 cm. in diameter which were somewhat firmer than the surrounding tissue.

Microscopically the spleen showed myeloid metaplasia with many megakaryocytes, nucleated red blood cells, compression of the malpighian corpuscles, which were few in number, and but little fibrosis.

The patient has had five subsequent admissions since removal of her spleen:

From November 8 to November 16 the patient entered because of severe epistaxis which could not be controlled at home by packing. This subsided after conservative treatment and one transfusion. While she was in the ward, a vesicular eruption developed on an erythematous base over the left forearm and chest. Biopsy was done of material from one lesion, and the condition was diagnosed folliculitis cheloidalis.

From Jan. 5 to Jan. 20, 1940 the patient returned because of abdominal cramps and diarrhea. There was no evidence of any acute abdominal condition. The hemoglobin content was 60 per cent, the red cell count 2,500,000 and the white cell count 16,000. There were many nucleated red cells. A gastrointestinal series was done and showed no pathologic conditions. The patient was given one transfusion and discharged.

From May 20 to May 21 the red cell count was 1,800,000, the hemoglobin content 41 per cent and the white cell count 18,700. The patient entered this time for a transfusion. She had been well, except for nocturnal pain in the chest radiating through to the back and progressive fatigue since her last admission.

From July 26 to July 30 the patient entered again for transfusion, complaining of weakness and fatigue. Physical examination showed the liver to be enlarged to the umbilicus for the first time. The heart showed a loud, blowing systolic murmur and gallop rhythm. The gallop rhythm disappeared after two 500 cc. transfusions. The reflexes were generally hyperactive throughout, and there was a transient ankle clonus present. She was somewhat improved on discharge. On admission the blood showed hemoglobin 25 per cent, red cells 1,200,000 and white cells 13,200. The smear showed many normoblasts.

November 19 to November 23 the patient was well until ten days before admission, when she had a severe, persistent, unilateral headache and had become progressively weaker during the preceding seven days. The hemoglobin content was 20 per cent, the red cell count 1,100,000 and the white cell count 9,700, with many normoblasts present. The icterus index was 5.0. A roentgenogram showed no osteosclerosis at this time. The fragility test showed hemolysis beginning in a 0.375 per cent salt solution and completed in a 0.300 per cent salt solution. The patient was somewhat improved on discharge.

The patient was readmitted on Feb. 4, 1941 with weakness and severe anemia. The blood showed a hemoglobin content of 8 Gm., 2,200,000 red cells and 4,800 white cells, with 37 per cent neutrophils, of which 5 per cent were nonfilamented, 46 per cent lymphocytes, 16 per cent monocytes and 1 per cent basophils. Platelets were normal. There were 4 per cent nucleated red cells per hundred white cells.

The bone marrow showed fibrosis. The remaining marrow was normal in cellular constituents. The patient was given two transfusions of 500 cc. of whole blood and discharged improved.

CASE 3.—M. E., an Austrian woman aged 48, entered the hospital on Dec. 16, 1937 because of a progressive weight loss of 22 pounds (10 Kg.) during the preceding year, along with frequent watery stools, occasional tarry stools, and the inter-

mittent passage of worms varying in length from 1 to 2 inches (2 to 5 cm.). She had had moderate anorexia during the few months before admission. She had not consulted a physician for these symptoms.

Her past history revealed that catamenia had ceased a little more than a year previously, with only one episode of vaginal bleeding, lasting eight days and accompanied by pelvic discomfort, thirteen months before. Otherwise the past history and the family history were noncontributory.

Physical examination showed that the woman was chronically ill, with slightly jaundiced scleras. There was no lymphadenopathy. The heart had a loud systolic murmur best heard over the base, with a blood pressure of 128 systolic and 60 diastolic. The entire left side of the abdomen was filled by a firm mass extending to the level of the umbilicus. No nodules were felt. The liver was likewise enlarged in the region of the flank to the level of the umbilicus.

Examination of the peripheral blood revealed hemoglobin 80 per cent; the red blood cell count was 4,200,000 and the white cell count 10,800, of which the differential count was mature polymorphonuclear cells 81 per cent, band cells 6 per cent, lymphocytes 3 per cent and monocytes 10 per cent. Reticulocytes constituted 1.2 per cent. Among the red cells there were many poikilocytes and microcytes. The icteric index was 8. The bleeding and clotting times were normal. Splenic puncture was suggested, but it was refused by the family physician, who desired the patient to have roentgen treatment to the spleen to shrink it. This was done, but after thirteen treatments of 200 roentgens, high voltage therapy was discontinued because of a low white cell count of 1,700, with 76 per cent polymorphonuclear leukocytes, 22 per cent lymphocytes and 2 per cent eosinophils. At this time the patient was discharged home to convalesce without a diagnosis having been made.

About two weeks later, on Jan. 22, 1938, the patient was readmitted for further study and treatment. The spleen had become enlarged in the interim since discharge and now reached almost to the iliac crests. The blood showed hemoglobin 59 per cent, red cells 3,000,000 and white cells 2,150; the differential count showed 84 per cent polymorphonuclear leukocytes (9 per cent band cells), 14 per cent lymphocytes, 2 per cent monocytes and 1 nucleated red cell per hundred white cells. On February 14 a splenectomy was done, no definite diagnosis having been reached preoperatively. The patient was given postoperatively a transfusion of 500 cc. of whole blood, and her convalescence was smooth. A check-up examination done on May 26 showed hemoglobin 89 per cent, red cells 6,000,000 and white cells 66,000; the differential count showed 40 per cent polymorphonuclears, 19 per cent band cells, 25 per cent lymphocytes, 10 per cent monocytes, 5 per cent eosinophils and 3 per cent basophils. There were 18 nucleated red cells and 2 erythroblasts per hundred white cells, urea nitrogen was 14.5, creatinine 0.5, uric acid 4.4, sugar 78, carbon dioxide 48.1, cholesterol 184 (free 59, or 32 per cent, ester 25), and in the galactose tolerance test all specimens were negative for galactose.

The Wassermann reaction was 2 plus on December 21 and negative on December 24. Total protein was 6.92, albumin 4.64 and globulin 2.28. Examination of the urine gave negative results.

Grossly the spleen was smooth, glistening, dark red brown and firm. On section the cut surface was similar in appearance to the liver, being homogeneously dark red, streaked here and there with lines of gray tissue and prominent channels.

Microscopically the spleen showed fibrous thickening of the capsule, trabeculae and reticulum. The malpighian corpuscles were reduced in number. There were megakaryocytes, myelocytes, plasma cells, eosinophils and a few polymorphonuclear leukocytes. There were no infarcts. A tentative diagnosis of Hodgkin's disease was made.

The patient had two subsequent admissions, July 17 to 19 and Oct. 22 to Nov. 7, 1938, both because of severe epistaxis, uncontrollable by packing at home. Transfusion was not necessary.

She was followed in the outpatient department from Nov. 10, 1938 until the present time. On Nov. 23, 1938 it was noted that the patient had a perforated septum. She continued to have epistaxis, which was treated locally with epinephrine and a thromboplastic substance. On Oct. 19, 1939 the patient complained of considerable itching of the legs. Roentgen treatment to the liver was given because of the diagnosis of Hodgkin's disease and to relieve itching. On Feb. 8, 1940 the patient complained of soreness of the tongue and bruising easily. By March severe glossitis had developed. The patient was given 100 mg. of nicotinic acid three times daily and two tablets of ferrous sulfate twice daily. On October 10 both glossitis and itching were somewhat improved. The skin was bronzed at that time. The liver was still enlarged, and the hemoglobin content was 15 Gm.

The patient was last seen on June 5, 1941. She had lost considerable weight, the liver was much enlarged and the skin was deeply bronzed. The blood showed hemoglobin 16 Gm., red cells 5,200,000 and white cells 41,000; the differential count showed polymorphonuclear leukocytes 51 per cent, of which 26 per cent were nonfilamented, lymphocytes 4 per cent, eosinophils 16 per cent, basophils 2 per cent, myelocytes 13 per cent and myeloblasts 4 per cent. The polymorphonuclear cells showed toxic granulations, and many abnormal platelets were seen.

CASE 4.—D. M., a German housewife aged 55, admitted to the hospital on Jan. 2, 1940, had noticed a swelling of the upper left portion of the abdomen five years before admission. The swelling was painless except for burning in this region on exertion. She had noted onset of weakness also at this time. The swelling had increased in size, and the patient had sought medical aid three years before admission. Since then she had had periodic courses of roentgen therapy, with a resulting decrease in the size of the mass, increased strength and amelioration of pain. The last roentgen treatment had been in May 1939, and she had entered the hospital for splenectomy, which was advised by her physician. There was no history of weight loss or jaundice. For an indefinite period she had had dyspnea and palpitation on climbing two flights of stairs. The family and past histories were not significant.

Physical examination showed her to be somewhat pale and only moderately ill. The upper teeth were missing, and the thyroid was of moderate size. There were pinguiculae in the conjunctivas. The heart was moderately enlarged to the left. There was a rough reduplicated first sound heard loudest at the apex. The blood pressure was 185 systolic and 100 diastolic. There were many brown nevi on the skin of the abdomen. The flanks were bulging and were dull with a moderate fluid wave. The spleen was enlarged to 3 inches below the umbilicus. It was firm, smooth, nontender and movable. The liver was enlarged to 4 fingerbreadths below the right costal margin. There was also a tender, rounded bulge in the right costovertebral angle which seemed to be independent of the liver.

Laboratory studies showed the hemoglobin content to be 85 per cent, the red blood cell count 4,200,000 and the white cell count 7,500, with mature polymorphonuclear leukocytes 72 per cent, band cells 5 per cent, young forms 5 per cent, myelocytes 2 per cent, lymphocytes 6 per cent, monocytes 4 per cent, eosinophils 3 per cent and basophils 3 per cent. The red cells showed anisocytosis, poikilocytosis and basophilic stippling. A sternal puncture showed essentially normal marrow. The fragility test of the red cells showed normal resistance to saline solution. The bleeding and clotting times were normal.

Because of the mass in the right flank, intravenous urographic examination was performed, which showed bilateral diminished renal function. The pelvis and calices were only faintly visualized.

On the eighth day after admission, splenectomy was performed after a preoperative diagnosis of Banti's syndrome. A biopsy specimen of the liver was obtained at the same time. Postoperatively the patient was given a transfusion of 500 cc. of whole blood. Save for mild pyelitis caused by *Escherichia coli*,

which responded to sulfanilamide, the patient's convalescence was uneventful. She was discharged one month after operation.

Biopsy of the liver showed myeloid metaplasia. The weight of the spleen was 1,895 Gm. The capsule was thin and glistening, although in one area it was thickened and yellow gray. Several small nodules, of a consistency similar to that of the surrounding tissue, projected through the surface. On section the cut surface was smooth, firm, beefy and pink red, with fine streaks of gray white running through it. The follicles were not visualized. Large amounts of fluid blood ran from the cut surface.

Microscopically the spleen showed diffuse fibrosis and infiltration with small round cells, polymorphonuclear leukocytes, eosinophils and giant cells, these last being very numerous. The sinusoids were congested with blood. The malpighian corpuscles were absent.

Two months after discharge the patient reported that she had gained 10 pounds (4.5 Kg.) and felt well. She was seen again on June 9, five months postoperatively, at which time her general condition was good. She complained of pain around the stomach, and there was a large mass in the region of the liver, the nature of which was unknown. She was advised to enter the hospital for a check-up but did not do so.

On Jan. 29, 1941 the patient was readmitted to the hospital with swelling of the ankles. She was found to have cardiac enlargement with a mitral systolic murmur. The blood showed hemoglobin 13.5 Gm., red cells 4,200,000 and white cells 134,000, with 84 per cent polymorphonuclear neutrophil leukocytes, of which 57 per cent were nonfilamented, 6 per cent myelocytes, 7 per cent lymphocytes, 1 per cent monocytes and 2 per cent eosinophils and there were 6 nucleated red cells per hundred white cells. The sternal marrow showed fibrosis, otherwise hyperplasia of the remaining granular elements. She was given digitalis and discharged improved.

CASE 5.—M. T., a Negro aged 48, admitted to the City Hospital on Sept. 7, 1940, had been well until three months prior to admission, when dyspnea on exertion and a productive cough developed. The cough was associated with pain at the costovertebral angles. Two months before admission he noticed that both ankles were swollen. During the previous three weeks the dyspnea had increased gradually, so that at the time of admission he was unable to walk without discomfort. He did not complain of orthopnea or pain in the chest.

A family history was not given. He had had an attack of "rheumatism" twenty-four years before and had had nocturia, urinating two or three times a night, for an indefinite period. Otherwise his general health had been good until the onset of his present illness.

On physical examination the patient looked somewhat older than his stated age and was lying quietly in bed. The blood pressure was 124 systolic and 58 diastolic. The pupils reacted sluggishly to light. The mucous membranes were pale and the teeth carious. Examination of the heart and lungs gave negative results. On admission, neither the spleen nor the liver could be palpated. There was edema (3 plus) of the ankles. Rectal examination showed hemorrhoids. There was a questionable generalized cervical adenopathy.

About a week after admission the spleen became palpable and gradually increased in size until death. Two weeks after admission the liver was felt, and it gradually enlarged until it was 3 fingerbreadths below the costal margin.

Examination of the blood on the day of admission showed hemoglobin 25 per cent, red blood cells 1,600,000 and white cells 86,000, with 28 per cent polymorphonuclear leukocytes, 24 per cent stab cells, 4 per cent metamyelocytes, 20 per cent myelocytes, 3 per cent granuloblasts, 3 per cent progranulocytes A, 3 per cent eosinophils and 10 per cent lymphocytes. The red cells showed anisocytosis and poikilocytosis, together with some nucleation of red blood cells. A fragility test showed hemolysis of the red cells beginning in a 0.5 per cent salt solution and complete hemolysis in a 0.32 per cent salt solution. The icteric index varied between 16 and 35. On October 17 the reticulocyte count was 8.5 per cent. Gastric analysis showed no free

hydrochloric acid. The nonprotein nitrogen level was 30. A Wassermann test done at this time gave negative results.

Roentgen examination of the chest showed some scarring in the left apex. Examination of the bones showed no osteosclerosis. Retrograde pyelography and tests of the function of the kidneys gave evidence of bilateral chronic pyelonephritis and hydronephrosis.

Examination of the urine on repeated occasions showed the presence of erythrocytes and white cells but no casts.

The patient's course in the hospital was one of progressive asthenia, despite repeated transfusions which resulted only in slight improvement. Terminally, bilateral bronchopneumonia developed; he became irrational, had a urinous odor to his breath and died nine weeks after admission (five months after the onset of his illness).

Autopsy showed, in addition to lesions of myeloid metaplasia, acute and chronic pyelonephritis, acute bilateral bronchopneumonia and fibrinous pericarditis.

The spleen weighed 700 Gm. The capsule showed many areas of thickening, and the parenchyma was firm and fleshlike. The pulp could not be scraped at all. Microscopically it showed typical myeloid metaplasia and many megakaryocytes.

The liver and lymph nodes also showed many megakaryocytes. The bone marrow obtained was erythroblastic in type.

COMMENT

In not one of these cases was the diagnosis, either clinical or pathologic, correct. The clinical diagnoses were splenic anemia in 4 instances and leukemia in 1. The pathologic diagnosis of the condition of the excised spleen (the slides were sent to several reputable pathologists) was either atypical Hodgkin's disease or atypical leukemia.

On the strength of the clinical diagnosis splenectomy was performed, and because of the pathologic diagnosis radiation therapy was occasionally employed.

From a perusal of the case histories it is evident that both splenectomy and radiation therapy are harmful in this condition. The causes of the myeloid metaplasia are not known, but removal or depression of any of the foci seems to shorten the lives of the patients. This fact is illustrated not only in our cases but also in those of Jackson's series. He notes 2 cases in which death occurred shortly after irradiation. Three of his patients and 4 of ours did badly after splenectomy. Therefore, from a therapeutic point of view it is important to be on the lookout for this syndrome. It is easily confused with Banti's disease, hemolytic anemia, splenomegaly and atypical leukemia. Sternal puncture will rule out leukemia, since no leukemic infiltration has been observed in the marrow of these patients. Banti's disease and hemolytic anemia do not show both immature red and immature white cells in the peripheral blood. Normal red cell fragility and absence of spherocytes also distinguish agnogenic myeloid metaplasia from hemolytic anemia.

In dubious cases a prolonged period of observation is advisable, and, if necessary, a splenic biopsy can be taken through the peritoneoscope. The presence of myeloid metaplasia, many scattered foci of immature red and white blood cells and megakaryocytes definitely establishes the diagnosis of agnogenic myeloid metaplasia of the spleen.

CONCLUSIONS

1. Agnogenic myeloid metaplasia of the spleen is difficult to diagnose and must be differentiated from Banti's disease, hemolytic anemia and leukemia.

2. Splenectomy and irradiation are definitely contraindicated.

ETHER ANESTHESIA IN THE PRESENCE OF PULMONARY TUBERCULOSIS

HENRY K. BEECHER, M.D.

AND

RALPH ADAMS, M.D.

BOSTON

Great and sometimes dangerous efforts are made to avoid the use of ether anesthesia when surgery must be carried out on patients who happen to be suffering from tuberculosis; accordingly, it is important to examine the basis for the prejudice against the use of ether for tuberculous patients. As will be observed, this prejudice does not appear to be established on a secure foundation. We have therefore studied the results of using ether in operations on a carefully followed series of patients and have compared our results with those from other clinics.

Our wish to give ether an adequate trial was based on extensive observations, made in many general surgery clinics as well as our own, that ether is extraordinarily well tolerated by the cachectic patient and by the patient whose respiratory and circulatory systems may be grossly impaired.¹

CURRENT BASIS FOR THE PREJUDICE AGAINST THE USE OF ETHER FOR PATIENTS WITH PULMONARY TUBERCULOSIS

Where the prejudice against ether originated is not clear, but the current basis for it can be found in many published opinions over the past twenty or thirty years.² These articles vividly describe the dangerous consequences of using ether anesthesia for tuberculous patients: It is plainly a bad agent to use, or so it is said, for "ether will dissolve the lipid capsule surrounding the tubercle bacilli and allow them to be disseminated throughout the body." Liquid ether burns the skin, and so on; therefore "it must follow that the delicate mucosa of the airway will be dangerously irritated by the agent." (A considerable difference must exist in the effect produced by liquid ether and the concentration needed for full surgical anesthesia, namely 0.14 cc. of liquid ether per thousand cubic centi-

From the Anesthesia and Surgical Services of the Massachusetts General Hospital.

This is the third in a series of papers dealing with the problems of anesthesia for thoracic surgery: (Principles of Anesthesia for Lobectomy and Total Pneumonectomy, *Acta med. Scandinav.*, supp 90:146, 1938, and the paper referred to in footnote 3).

1. In addition to the use of ether in a large number of patients at the Massachusetts General Hospital, with nearly all kinds and degrees of heart disease, ether has been our choice for patients suffering from many forms of chronic pulmonary disease as emphysema, chronic bronchitis, chronic lung abscess, bronchiectasis and cancer. In the surgical treatment of these, ether has been employed as the anesthetic agent of choice in 65 total pneumonectomies and 222 lobectomies with unusually good end results.³

meters of air breathed.) Evidence that irritation from good ether anesthesia is probably not of morbid or mortal importance has been considered elsewhere.³ This probability receives outstanding support in the observations of King⁴ and others that an equal number of postoperative pulmonary complications are found in general surgery after ether, local or spinal anesthesia.

While opinions are divided at present concerning the advisability of using ether in operations on tuberculous patients, as shown in the following examples, there have been more to oppose than to approve or condone its use.⁵ Following correspondence with about one hundred anesthetists, surgeons and internists, Eastman⁶ found a great lack of unanimity of opinion as to the advisability of employing ether in the presence of pulmonary tuberculosis. Indeed, opinion varied from the conviction that ether would cure the tuberculosis to the belief that its use in operations on tuberculous patients is unqualifiedly foolhardy and, if administered to tuberculous patients, "sends them to their graves in less than six months." Unfortunately the statements of those questioned appeared to be made on the basis of memory and opinion rather than on a serious attempt to get at the facts through careful observation and record keeping.

Grandy⁷ presents a vigorous condemnation of ether administered by inhalation to patients with pulmonary tuberculosis, and then at once speaks approvingly of ether by rectum. He concluded with the remark "I shall give only these 2 cases [of active tuberculosis] but these are enough to prove [!] that ether administered by rectum is entirely different from ether by inhalation." Among those who permit ether to be considered at all, this attitude is quite common. It ignores, of course, the well established fact that ether is almost entirely (above 90 per cent) excreted through the lungs. The alveolar air at once comes into near equilibrium with the ether tension in the blood, so that throughout maintenance and recovery the lungs are exposed to ether at the same tension, except for the brief induction period, as they would have been if the ether had entered through them rather than through the rectum. When ether is administered rectally, the difficulty of correlating the dose with the desired depth may in some cases be responsible for needlessly high concentrations reaching the lungs and acting for a longer time than when ether is given by inhalation.

While many papers have been found which deal with the use of ether in the presence of pulmonary tuberculosis, no report of careful case studies has been found. The articles referred to, apparently chiefly based on casual memory and opinion, seem to be the basis for the widespread belief as expressed in standard textbooks that ether is contraindicated or to be used with the greatest reluctance in the presence of tuberculosis.

EXPERIMENTAL STUDIES OF THE PAST CONCERNING THE USE OF ETHER IN THE PRESENCE OF PULMONARY TUBERCULOSIS

It is interesting to observe that whereas severe condemnation of ether for the tuberculous is common in the papers based on opinion, the three objective attempts

to study the problem experimentally have come to quite another conclusion:

Corper⁸ observed that ether to the point of light anesthesia daily for about a month did not increase the susceptibility of guinea pigs to a virulent human tuberculous infection in comparison with controls.

Lawrason Brown and Petroff⁹ studied three groups of tuberculous guinea pigs. In each of the first two groups, 4 pigs were exposed to ether anesthesia and 4 used as controls. In the third group 3 pigs were used in each test and control group. In the first group, two weeks following infection, ether anesthesia was administered at weekly intervals for seven weeks. The etherized group lived longer than the controls. The second group was treated the same as the first except that anesthesia was administered every four days. The etherized and control animals lived the same length of time. In the third group anesthesia was administered daily for fifteen days, and then the animals were killed. The tuberculosis was equally extensive in the test and the control groups. They conclude that "ether anesthesia, whether prolonged or of short duration, whether light or profound, exerts on tuberculous guinea pigs no injurious effect as noted in length of life or extent of disease."

Rogers¹⁰ subjected 18 guinea pigs to tubercle bacillus infection; half received "complete ether anesthesia" daily for eleven days and half were used as controls. The duration (5 pigs) and extent (4 pigs) of the disease were identical in the two groups. He concluded that ether anesthesia has no effect on the disease process of tuberculosis.

Corper,⁸ Brown and Petroff⁹ and Rogers¹⁰ have all reported that repeated ether anesthesia in tuberculous animals does not result in a more rapid spread of the disease process. Rogers concludes that the "rapid spread of the disease [which] often followed operations on the tuberculous under ether anesthesia" is due to mechanical factors. He suggests that spread of the disease is due to "aspiration from the apical lesion, usually a cavity, to the larger areas of the lung substance, causing aspiration bronchopneumonia and after a few months death." Any factors such as labored respiration or excessive body movements aid in this aspirating process, according to him. He states further that "ether anesthesia not only causes labored respiration but increases the secretions diluting the infectious germ laden sputum and in this way causes a general spreading of the disease germs." He goes on to say that, "in the laboratory animal, the disease is anatomically different, inasmuch as the chronic ulcerative form is not present, but more of a solitary tubercle formation without ulceration, hence the aspirating of infectious material does not occur."

Whether or not Roger's explanation is correct, it is interesting that the only objective examinations made of this problem, the experimental studies, fail to provide any grounds for discrediting the employment of ether for the tuberculous patient. While the experimental studies leave much to be desired in their attack on the problem, it is probably true, as suggested by Rogers,

that the tuberculosis process is sufficiently different in guinea pigs, ulcerative pulmonary lesions and cavities so rare in them, that the problem at hand cannot be settled by such an approach. With the possible exception of studies in monkeys it is questionable whether any animal experimental work would be of further

TABLE 1.—Type of Operation and Duration of Anesthesia in 147 Cases

value in giving information on the problem at hand; certainly any attempts to get more help from animals would have to be very extensive. However, the three independent studies referred to, having arrived at a common conclusion, need not be passed by entirely. This negative evidence thrice obtained is of some value. Evidently the belief that the lipid solvent action of ether is a danger is on a less secure basis than has been supposed. It is apparent that, even in the highly susceptible guinea pig, ether anesthesia does not aggravate the disease process. This point at least can reasonably enter to a limited degree into our consideration.

While statements based on opinion appear to have served as the basis for the numerous strictures against ether in the tuberculous, so many men have been of this view that one cannot lightly dismiss their statements. A point worth noting here is that nearly all, if not all, of the statements referred to were based on open cone anesthesia, not modern, closed anesthesia. Surely open cone anesthesia is objectionable in these cases (and in many others) for several reasons: The vapors breathed are cold. One must deal not only with possible irritation due to the ether itself but also with that due to chilling the lungs. With less than expert cone administration of ether, the concentration of the agent breathed will at times be very much greater than needed and consequently more irritating than necessary. In the great majority of cases, cones are used in a manner that serves to increase considerably the dead space of the airway, with an objectionable elevation of the carbon dioxide tension and a lowering of the oxygen in the air breathed. Often the so-called open cone is nothing short of an asphyxiating tool.

With the simple modern equipment at hand, it is easy to avoid these difficulties encountered with the open cone. We believed that ether employed in modern closed anesthesia with the carbon dioxide absorption technic is worthy of trial and reevaluation in tuberculosis, for, as pointed out earlier, ether has many desirable qualities for the very sick. Ether administered in a closed system can hardly be compared with the agent when it is used by the open drop method.

Accordingly, we have carefully studied for a period of more than five years a series of patients who received "closed" ether anesthesia, notwithstanding their pulmonary tuberculosis. Our major purpose in this paper is to report that experience.

USE OF ETHER IN THE PRESENCE OF PULMONARY TUBERCULOSIS AT THE MASSACHUSETTS GENERAL HOSPITAL

We began to use ether routinely as the anesthesia of choice for thoracoplasty in patients with pulmonary tuberculosis in October 1935. This beginning was made under the direction of Dr. H. H. Bradshaw. The present study concerns consecutive patients treated from that date through 1940: 229 tuberculosis patients received ether anesthesia for four hundred and four thoracoplasties during this period. While the majority of the patients came from the Rutland Sanatorium, a number of other sanatoriums participated. Since more precise follow-up information was available concerning the Rutland patients, we decided to limit our study to this group: 147 patients who underwent two hundred and sixty thoracoplasties under ether anesthesia.

Details concerning choice of patient for thoracoplasty, surgical indications and procedures and similar material are recorded in a recent paper from this clinic by Adams and Dufault.¹¹ The routine premedication consists of morphine sulfate $\frac{1}{2}$ grain (0.01 Gm.) and atropine $\frac{1}{100}$ grain (0.00065 Gm.) administered subcutaneously one-half hour before operation. Frequently, soluble pentobarbital $1\frac{1}{2}$ grains (0.1 Gm.) is given by mouth one hour before operation. Patients are placed in position for operation before anesthesia is induced. During induction, care is taken to prevent straining and coughing. The choice of operating time is the afternoon, following elimination of the morning sputum. Anesthesia is administered by means of a closed system apparatus with carbon dioxide absorption (never open cone for these patients). Following a brief nitrous oxide-oxygen induction, with care to avoid anoxemia, ether anesthesia is administered with a high percentage of oxygen. Although intratracheal tubes are used with great frequency in this hospital and are always used in open pleura operations, we rarely use them in the presence of pulmonary tuberculosis. They are used in this case only when the sputum is unusually abundant. We are reluctant to use them in most cases of tuber-

TABLE 2.—Results * of Thoracoplasties (Including Tuberculous Empyema)

The 21 patients operated on in 1940 have not been included in this and result table, since a one year follow-up is not adequate for indicating disposition; yet all of the operative complications as anoxia and shock, pneumonia and atelectasis as well as spread occurring in the 1940 patients have been included in the complications; see table 3.

* According to the National Tuberculosis Association's method of classification.

† That is, within the customarily stated but purely arbitrary two month period following operation.

culosis, for possibly new loci of tuberculous infection might develop in areas of slight trauma to the airway. During operation the patient is maintained in a slight Trendelenburg position.

With termination of the study reported here, at the end of December 1940, all patients will have been

11. Adams, Ralph, and Dufault, Paul: Surgery in Pulmonary Tuberculosis, J. Thoracic Surg. 11: 43 (Oct.) 1941.

followed for at least one year after their last anesthesia and operation. It would seem reasonable to suppose that damage possibly caused by the anesthesia would become evident within that time. The "end result" data of table 2 run only until the end of 1939; thus these patients have all been followed for at least two years.

It is unquestionably important in computing end result data in a study of this kind to consider the number of patients studied rather than the numbers of anesthetics and operations; nevertheless, in order to show distribution of type of operation, and frequency and duration of repeated anesthetics, the number of operations has occasionally been considered, as in table 1.

As shown by the study of Adams and Dufault¹¹ the patients coming from the Rutland Sanatorium to the Massachusetts General Hospital for treatment of their pulmonary tuberculosis gave the following distribution of conditions requiring surgery: cavernous disease, 87 per cent; pulmonary tuberculosis and tuberculous empyema, 5 per cent; pulmonary tuberculosis and mixed empyema, 5 per cent; unstable fibrotic disease without demonstrable cavitation, 3 per cent; early bronchial disease, 1 per cent. Our material deals with consecutive cases from the Rutland Sanatorium; those having tuberculous empyema as well as other unfavorable complications are of course included. The composition of the surgical teams changed frequently. The surgeons varied from members of the house staff to the chief of service.

TABLE 3.—*Postoperative Complications*

(Total number of patients, 147; total number of operations, 260)

Complications	Number	Per Cent Based on Number of Patients	Per Cent Based on Number of Operations
Anoxemia and shock.....	3	2.0	1.2
Pneumonia.....	4	2.7	1.5
	4	2.7	1.5
	5	3.4	
	3	2.0	

This table, based on the "early" complications (within two months), does not include wound infection (5 cases), late secondary wound hemorrhage (1 case) or torn pleura (1 case), since these are clearly unrelated to anesthesia, although these are all set down in the brief case summaries.

COMPLICATIONS AND DEATHS

Of the 147 patients (two hundred and sixty anesthetics and operations) the early complications and deaths are summarized here. This "early" group covers the customarily stated but purely arbitrary period of two months following operation. The "late" complications and deaths are subsequently grouped together.

EARLY

D. P. D., 1935. A man aged 24 died of ipsilateral, acute bronchiogenic spread of tuberculosis nineteen days after the third stage operation.

J. J. O'L., 1935. A man aged 20 died two days after first stage thoracoplasty and apicolysis of shock and anoxemia.

T. H., 1936. A man aged 30 died five weeks after first stage thoracoplasty of anoxemia, atelectasis, hemoptysis and ipsilateral spread of disease.

W. T., 1936. A man aged 26 developed bronchopneumonia two days after first stage thoracoplasty. This completely cleared within two months. After a second stage operation he is now well and working.

R. L., 1936. A man aged 36 was cyanotic following a first stage thoracoplasty. He was completely relieved by circulatory stimulants and oxygen. Surgical shock followed a second stage operation; this was combated successfully with intravenous saline solution.

S. P., 1937. A woman aged 36 died three days after a second first stage thoracoplasty with apicolysis (bilateral first stages and one second stage) of hemolytic streptococcus wound infection.

J. W., 1937. A man aged 46 developed bronchopneumonia four days after a second stage thoracoplasty; this cleared within three weeks.

R. K., 1937. A man aged 48 died five days after a second stage operation of shock and prolonged circulatory failure.

M. MacF., 1937. A woman aged 37 died five days after a third stage thoracoplasty of atelectasis and anoxia.

E. McC., 1937. A man aged 25 died eight days after a second stage thoracoplasty of wound infection.

A. P., 1938. A man aged 27 died one month after a third stage thoracoplasty of major hemorrhage in wound.

J. T. H., 1938. A man aged 46 showed ipsilateral spread of disease within three weeks of a first stage thoracoplasty. He died one year later of progression of the disease.

C. G., 1938. A man aged 41 developed atelectasis, after a first stage thoracoplasty, the day of operation. This persisted for six days, then cleared.

P. Q., 1938. A woman aged 37 with bilateral cavitation showed exacerbation of the process contralateral to operation within two weeks of a first stage thoracoplasty.

M. E. H., 1938. A woman aged 32 suffered a torn pleura during a second stage thoracoplasty with resulting pneumothorax.

G. C., 1938. A man aged 47 immediately after a first stage thoracoplasty developed bronchopneumonia which persisted for twenty-three days. This was followed by ipsilateral spread of the disease and death one year later.

W. E. G., 1938. A man aged 30 showed, twelve days after a first stage thoracoplasty, signs of a contralateral spread. These cleared in four months and a second stage operation was performed.

R. P., 1939. A man aged 41 with bilateral cavernous tuberculosis developed bilateral bronchopneumonia two days after a first stage thoracoplasty. This cleared in two weeks.

J. K., 1939. A man aged 23 had wound infection and ipsilateral spread within a week after a first stage thoracoplasty.

W. J. F., 1940.¹² A man aged 44 with bilateral tuberculosis showed major wound infection and contralateral spread of tuberculosis following a first stage thoracoplasty. Death was caused by the wound infection and progressive cavernous tuberculosis two months after operation.

R. U., 1940.¹² A man aged 34 developed atelectasis three days after a first stage thoracoplasty. The reaction required twenty-eight days to subside. Later a second stage operation was performed without unusual incident.

J. D., 1940.¹² A man aged 27 died thirteen days after a second stage operation, of wound infection.

LATE

G. B., 1935. A woman aged 26 died of progression of tuberculosis one year after a first stage thoracoplasty.

A. F. J., 1935. A man aged 36 died of progression of tuberculosis eight months after a first stage thoracoplasty.

J. F. O'C., 1936. A man aged 32 died of intestinal obstruction caused by tuberculosis two years after a second stage thoracoplasty.

M. F., 1937. A man aged 26 died of progression of pulmonary tuberculosis and extrapulmonary tuberculosis nine months after a third stage thoracoplasty.

J. W., 1938. A man aged 47 died of progression of his disease, six months after a second stage thoracoplasty.

J. T. H., 1938. (Included in preceding "early" group, which see, since it showed early spread of disease but was classified as a late death.)

G. C., 1938. (Included in preceding "early" group because of early complications. Classified as a late death.)

W. J., 1938. A man aged 31 died of progression of disease and wound infection eight months after a first stage thoracoplasty

COMPARISON OF OUR RESULTS WITH THOSE
FROM VARIOUS CLINICS

In our series of 126 cases of thoracoplasty for tuberculosis from 1935 through 1939 under ether anesthesia there have been eight early deaths (6.3 per cent), that is, within the customarily stated but purely arbitrary period of two months after operation, and eight later deaths (6.3 per cent) for a total death rate of 12.7 per cent from tuberculosis in any form and from causes directly or indirectly connected with the operation; 59.5 per cent of the 126 cases are apparently cured, 8.7 per cent arrested, 1.6 per cent apparently arrested and 14.3 per cent quiescent.

Haight and Alexander¹³ reported a death rate of 5.6 per cent in 178 cases between 1934 and 1937 from causes directly or indirectly connected with operation,

TABLE 4.—Averages in Seven Groups of Cases *

Authors	Major Anesthetic Agent	Cases	Early Death Rate	Total Death Rate	Apparently Arrested and Apparently Cured
Aufses.....	Nitrous oxide.....	90	7.0	11.0	71.0
Diffenbach and Crecca	Evipal plus nitrous oxide	100	2.0	13.0	71.0

Average (with standard deviations)		129	4.5±0.9	10.0±1.9	71.5± 3.0

* It is impossible to determine from some of these series whether or not patients having emphysema were included. The inclusion of emphysema cases interferes greatly with good average end result figures. All emphysema cases that we encountered in the consecutive cases studied were included in our data.

† If we include our quiescent cases here, as some writers appear to have done, 69.8 per cent becomes 81.1 per cent. It was not possible to break down the data from the several clinics presented here as they should be according to the National Tuberculosis Association classification; namely, as apparently cured, arrested, apparently arrested and quiescent. Our figures for these respective groups are shown in table 2.

and a total death rate of 6.1 per cent. In another group of 119 cases, probably including many of the foregoing, they had 83.1 per cent apparently arrested cases from two and one-half months to two years after operation. At the time these data were compiled, nitrous oxide was chiefly favored by Alexander as the anesthetic agent (pp. 443, 444, 448).

Skinner, Macpherson and Allen,¹⁴ report 3.2 per cent early deaths and 4.8 per cent total tuberculous deaths in a series of 126 cases from 1936 to 1940. The anesthesia which they used (personal communication) was avertin with amylene hydrate plus nitrous oxide in nearly all cases. Cyclopropane was used in a few cases.

Finney¹⁵ had an operative mortality of 5.7 per cent and a total mortality of 18.2 per cent in a group of 104 cases between 1932 and 1940, with arrest of disease in 42.3 per cent and apparent arrest in 20.2 per cent.

13. Alexander, John: The Collapse Therapy of Pulmonary Tuberculosis, Springfield, Ill., Charles C. Thomas, 1937, pp. 562, 564.

14. Skinner, G. F.; Macpherson, Lachlan, and Allen, Irene: Thoracoplasty for Tuberculosis, J. Thoracic Surg. 11: 54 (Oct.) 1941.

15. Finney, G. G.: Analysis of 104 Cases of Thoracoplasty for Pulmonary Tuberculosis, J. Thoracic Surg. 11: 76 (Oct.) 1941.

Avertin with amylene hydrate and nitrous oxide-oxygen were used in the earlier cases and cyclopropane in the later ones.

Meltzer,¹⁶ using local anesthesia exclusively, reported that he obtained arrest of disease in 32 per cent and apparent arrest in 31.4 per cent of 181 patients from 1936 to 1941, with an operative mortality of 1.6 per cent and a total mortality of 4.4 per cent.

Aufses¹⁷ had an operative death rate of 7 per cent and a total death rate of 11 per cent in 90 cases between 1935 and 1940, using nitrous oxide-oxygen, avertin with amylene hydrate and cyclopropane, and the disease of 71 per cent of his cases was arrested.

Diffenbach and Crecca,¹⁸ using evipal and nitrous oxide-oxygen, reported 100 cases in which operation was performed during the period 1936 to 1938, with an early mortality of 2 per cent, a total mortality of 13 per cent and arrest of disease in 71 per cent.

The averages for these seven groups of cases are shown in table 4. Except for the figures from Haight and Alexander, the data are the most recent published, representing the authors taking part in the Symposium on Results from Thoracoplasty at the twenty-fourth annual meeting of the American Association for Thoracic Surgery, Toronto, Canada, in June 1941.

It is apparent that the results in our cases have fallen near the average in the several categories. On the basis of these comparative data, no outstanding virtue can be claimed for one anesthetic agent nor particular hazard charged against another, as far as the results in these seven series go. Certainly it is true here as elsewhere that the anesthetist is of more importance than the anesthetic agent employed. To let one's conclusions rest here, however, implies a rather restricted view of the matter. It seems to be true that any one of two or three agents can safely be employed in the presence of pulmonary tuberculosis without aggravating this disease process. One might assume therefore that, if a well trained anesthetist is available, these two or three agents are all equally desirable. We doubt the validity of such an assumption, for it implies that the absolute death rate is the same for all of these agents. While it is admittedly difficult if not impossible to get precise information on this subject, enough evidence is available to indicate that wide differences exist between the death rates of the common anesthetic agents. Since this is the case it seems wiser to choose the agent which allows two important things: (1) the lowest death rate when large masses of data are considered, in other words jeopardizes the patient the least, and (2) permits the surgeon the greatest freedom. The low death rate of ether has been established in general surgery from its use in very sick patients in many hundreds of thousands of cases. The death rates of some other common general anesthetic agents appear to be at least twice as high as that of ether. In addition to these matters, the following should be considered: When the anesthesia is to be chosen for thoracoplasty, we believe it to be of great importance to choose ether, for on the basis of a considerable experience with patients who undergo all kinds of thoracic surgery it is our observation that many of the obvious as well as less apparent difficulties encountered during these operations are caused by reflex phenomena medi-

ated through the vagi. The depression of vagal activity accomplished by ether is of real importance in thoracic surgery. We have reached this conclusion on the basis of data obtained in the clinic as well as in the anesthesia laboratory. In this regard ether exceeds in value all other agents studied to the present time.

Since the choice of closed ether anesthesia presents no hazard to the tuberculosis process, as far as we have been able to determine, it appears to us to be the best choice for the reasons that have been mentioned, for use in operations on patients who are suffering from tuberculosis whenever they require general anesthesia, whether this is for surgical treatment of pulmonary tuberculosis or for surgical treatment of other lesions.

SUMMARY

A prejudice exists against the use of ether anesthesia for operations on tuberculous patients. Where this originated is uncertain, but the current basis for it can be found in numerous published statements. On examination, these statements do not appear to be founded on study and careful record keeping; casual opinion appears to have served as the basis for many of the statements voiced against ether. Three groups of workers have in the past attacked the problem experimentally. Not one was able to substantiate the prejudice against the use of ether anesthesia for operations on the tuberculous. Most of the articles which apparently serve as the basis for the current prejudice against ether were written from one to three decades ago and were based on observations of "open cone" or "open drop" ether administration. It is probable that some of the secondary results of the use of this technique are undesirable in the presence of pulmonary tuberculosis as elsewhere.

Since the prejudice against the use of ether anesthesia for operations on the tuberculous does not appear to be based on a secure foundation and since, as far as we have been able to find, no extensive clinical study of this matter has been carried out, we have for more than five years been using closed ether anesthesia (with carbon dioxide absorption) in operations on consecutive patients undergoing surgical treatment of their pulmonary tuberculosis. Our data include all cases, favorable and unfavorable. The surgical teams were constantly changing, the surgeons varying from members of the house staff to the chief of service. Notwithstanding these facts, our results for more than five years are such as to compare favorably with those from other clinics where ether is used either not at all or rarely.

In our opinion, the anesthetic agent is not important in these cases as long as it permits the use of a plentiful supply of oxygen and allows the surgeon to carry out a deliberate, unhindered and unhurried operation, provided the patient is not jeopardized by toxic action of the anesthetic. It is important to choose an anesthetic agent which depresses vagal activity when thoracic surgery is contemplated. Ether excels other agents studied in this regard. While not enough data have been collected to permit final statement, several of the newer anesthetic agents appear to have a death rate in general surgery two or three times higher than is the case with ether. The excellent tolerance of the very sick patient for ether anesthesia as well as the low death rate attributable to this agent are well established. After five years of study we can see no reason to abandon the use of ether in operations on the tuberculous patient because of the presence of tuberculosis.

UNTOWARD EFFECTS OF PHENYTOIN SODIUM IN EPILEPSY

ISIDORE FINKELMAN, M.D.

AND

A. J. ARIEFF, M.D.

CHICAGO

Merritt and Putnam¹ found that while phenytoin sodium (sodium diphenyl hydantoinate, or dilantin sodium) was effective in protecting animals from electrically induced convulsions it produced little sedative effect. The effectiveness of this drug was then determined by them² in a group of 200 patients who had been having frequent convulsive seizures for many years and who had obtained little or no benefit from the usually accepted treatment. Certain toxic effects were observed, among them dermatitis, nonthrombopenic purpura, tremors, ataxia and dizziness.

Although Fetterman³ reported that phenytoin sodium had a high degree of therapeutic value, he observed disquieting side actions such as itching, a cutaneous rash, swelling of the gums, tremors and ataxia, blurring of vision, loss of taste and dysesthesia in the mouth, restlessness, insomnia, irritability, paranoid state, anorexia, gastric distress and loss of weight. A study of the table published by Fetterman shows that 23 of 28 patients, or 82 per cent, had some toxic effects. Epistaxis was mentioned by Frost⁴ as a complication. Kimball⁵ reported hyperplasia of the gums. Merritt and Putnam⁶ later mentioned diplopia with nystagmus, drowsiness, headache, psychotic reaction, hypertrophy of the gums and slight secondary anemia in a small percentage of patients. Blair, Bailey and McGregor⁷ reported the side effects of giddiness, tremor, ataxia, blurring of vision, slight nausea, delusions, hallucinations, prolonged confusion, clonic spasms, agitation, mental depression and reactivation of suicidal tendencies in an unspecified number of their 75 institutionalized patients treated with phenytoin sodium. Toxic reactions in some degree occurred in the majority (73 per cent) of Pratt's 52 cases.⁸ In addition to the usual side actions such as subjective tremulousness and a feeling of apprehension and tension, tremors, burning sensation in the eyes, blurring of vision, diplopia, dizziness, ataxia, nausea and vomiting, 5 patients had psychotic states. Blair⁹ reported a case of hemiplegia developing as a complication of treatment with phenytoin sodium. He¹⁰ later reported the results of treatment of 36 institutionalized patients with phenytoin sodium. Twenty-one, or 58.3 per cent, developed severe nervous toxic symptoms. Of particularly ominous nature seemed

psychosomatic delusions, revival of such psychotic symptoms as severe depressions and the like. Loss of weight was frequent, occurring in 15 out of 20 patients. Eosinophilia (between 4 and 12 per cent) occurred in a few cases and in 2 cases a reduction in red blood cells occurred. Pratt⁸ found a mild albuminuria in some cases. McCartan and Carson¹¹ reported that toxic symptoms developed in 40 per cent of their 20 cases. In some of their cases a decided twitching of the orbicularis oris preceded by two to three weeks the development of ataxia. In every case there was a slight, progressive diminution of the red cell count. There was a tendency to a lowering of the white cell count due to a fall of granulocytes. In 13 cases (65 per cent) there was a rise in the number of eosinophil cells.

Williamson¹² reported severe toxic effects of phenytoin sodium in mentally defective patients with epilepsy. He said that these toxic reactions were clinically identifiable with a state closely resembling nirvanol poisoning. Of the toxic reactions, Williamson noted widespread furunculosis in 1 case, edema of the face in 2 cases, an urticarial wheal along the mucocutaneous margin of the lips in 1 case and gingival hyperplasia with bleeding in 1. There was 1 case in which there was a persistently low blood urea and 2 cases in which there was hematuria. There were 4 deaths among the 20 patients treated, or a mortality of 20 per cent. In the cases terminating fatally oliguria was the rule. An intermittent temperature of 100 to 102 F. appeared late. In 1 case it rose to 106 F. forty-eight hours before death, while in other cases the terminal temperature was subnormal. Death was due to bronchopneumonia in 1 case and to status epilepticus in 3. Status epilepticus set in in the 3 cases after phenytoin sodium therapy had been administered for one-half month, one-half month and two and one-half months respectively. In 1 case the treatment was discontinued after three months because a tendency to status epilepticus began.

Williams¹³ reported that 2 patients died in status epilepticus while on phenytoin sodium and bromides. Phenytoin sodium had at first obviously had a good therapeutic effect, yet status epilepticus later developed while the patients were under full treatment with the drug. Status developed in 1 case after a remission of five weeks while on treatment and in the other after a remission of two months while on treatment. He also found that toxic symptoms arose in 36 per cent of his 83 patients. The toxic complications involving the nervous system included bifrontal headaches, lethargy, bilateral ptosis, blurring of vision, diplopia, ataxia, tremor and nystagmus in all directions. Behavior disturbances also occurred which might be attributed to the toxic effects of phenytoin sodium.

Blair¹⁰ reported 4 deaths but could not definitely prove the association of death to the use of phenytoin sodium. In 1 case phenytoin sodium was withdrawn long before death. One death was due to cardiac involvement in a patient with known cardiovascular disease. In the other 2 cases, however, postmortem examination showed myocardial damage, and we believe that phenytoin sodium had a toxic influence on the myocardium leading to a fatal termination.

Blair¹⁰ also noted in 4 cases a noticeable exacerbation of spells following a long period free from spells

due to phenytoin sodium therapy. An increase of phenytoin sodium dosage led to an increase of seizures. Reduction of the dose led to a reduction of the seizures.

Coope and Burrows¹⁴ had 2 fatalities due to bronchopneumonia following an acute exacerbation of seizures: a woman aged 31 had a series of six severe major attacks after three weeks on phenytoin sodium therapy and three seizures the next day. Phenytoin sodium was discontinued and she was given bromides, a chloral derivative and phenobarbital, but she had fifteen attacks the following day. Three days later she died of bronchopneumonia. The other patient who died was a youth aged 18 who after two weeks on phenytoin sodium therapy had two seizures. After two more weeks he had two, four and nineteen spells on successive days, his temperature rose to 105 F. and he died of a disseminated bronchopneumonia.

Kimball and Horan¹⁵ reported repeated attacks of gastrointestinal irritability together with unusual hyperplasia of the gums. Mandelbaum and Kane¹⁶ reported a case in which there was pyrexia, dermatitis exfoliativa and considerable enlargement of the liver and spleen. The serum phosphatase value was found to be increased to 15.4 mg. per hundred cubic centimeters. Phenytoin sodium was given in 1½ grain (0.1 Gm.) capsules two or three times a day. The rash was first noted after thirty-nine capsules had been taken and the more severe toxic effects occurred after seventy-nine capsules had been ingested.

Aring and Rosenbaum¹⁷ reported that a young man on three occasions ingested 60, 90½ and 105 grains (4, 6 and 7 Gm.) of phenytoin sodium over a period of minutes, six hours and ten hours respectively. The chief resulting symptoms were exhilaration, light headedness, dizziness, nausea and vomiting, headache, staggering, diplopia, nystagmus, difficulty in converging the eyes, pupillary abnormalities, ataxia, tremor and changes in reflexes. Of all these signs, nystagmus persisted the longest and was present for eight days on the last occasion.

OUR OBSERVATIONS

Forty-four patients with epilepsy who had previously been treated with bromides or phenobarbital for at least six months were each given from 0.3 to 0.6 Gm. of phenytoin sodium daily. Four of these patients were from the private practice of Dr. L. J. Pollock. The remainder were from the Epilepsy Clinic of Northwestern University Medical School. Phenytoin sodium was administered according to the method advised by Merritt and Putnam. The previous medication was gradually withdrawn as phenytoin sodium was overlapped and finally substituted. Treatment was begun on 20 patients in April 1939. As patients were found suitable for this treatment they were added shortly after that date until a total of 44 was reached. However, at the present time only 7 patients remain on active treatment with phenytoin sodium.

The reasons for discontinuing the medication after varying lengths of time from two weeks to several months were as follows: It was discontinued in 3 cases because of an increased frequency of spells, in 6 because of a severe ataxia, in 1 because of a severe gastrointestinal disorder, in 7 because there was no reduction in the number of seizures, in 4 because psychotic

behavior developed, in 4 because of the development of an encephalopathy, in 3 because there were electrocardiographic changes and subjective complaints of precordial distress, in 5 because of irritability and apprehensiveness and the refusal of treatment and in 1 because of the development of peripheral neuritis.

TOXIC EFFECTS

The most alarming side effects were those involving the nervous system. The gastrointestinal tract, the cardiovascular system, the skin and formed elements of the blood also exhibited evidence of deleterious effects of phenytoin sodium. Each patient presented more than one symptom of a disquieting side effect involving various organs.

Ataxia, tremor and nystagmus were the most frequent symptoms reflecting toxic action on the nervous system. The ataxia was of the cerebellar type and the Babinski-Weil sign was frequently elicited. Many of the patients were irritable and apprehensive and said they were "jittery." The most serious complication was the development of an encephalopathy or a psychosis necessitating institutionalization. An encephalopathy occurred in 4 cases. A loss of weight in our experience was an indication of the development of toxic symptoms leading to an encephalopathy. One patient aged 15 who had a remission for six months while on phenytoin sodium therapy began losing weight gradually for a period of four months, although she said that she was eating too much. Her attention was wavering for several weeks and then she became somnolent. She had no subjective complaints but she walked slowly and stared as though in a trance. Then she complained of dizziness and mild nausea. She became very sleepy, mumbled to herself and was very unsteady in gait. Nystagmus was present laterally and vertically. A positive Babinski-Weil reaction was elicited. There was considerable swaying during the Romberg test. There was a facial weakness on the right side, hyperactive deep reflexes, absent superficial abdominal reflexes and no pathologic reflexes. She answered to questions only with yes or no very slowly. She became semistuporous.

This type of encephalopathy had developed in 4 cases. The psychotic behavior that occurred in 6 cases was characterized by a confusional paranoid state with significant irritability.

There were 2 children who had tantrums of temper consisting of stamping on the floor, walking around in circles and throwing themselves on the floor while on treatment. This behavior had not occurred on previous medication and their behavior may have been due to the toxic effects of phenytoin sodium. Other side effects involving the nervous system were vertigo and dizziness, paresthesias, peripheral neuritis (1 patient), headache, visual disturbances including blurring of vision and diplopia, insomnia, somnolence and general weakness.

Two of the patients developed status epilepticus, 1 after four weeks on phenytoin sodium 0.4 Gm. daily and the other after a week of treatment with 0.3 Gm. daily and phenobarbital 2¼ grains (0.15 Gm.) daily. Five patients had an increase in the frequency of spells. Others have reported, as already mentioned, status epilepticus as a complication of phenytoin sodium. It is possible that one of the toxic effects of phenytoin sodium is an increase in the frequency of seizures and status epilepticus.

The heart was studied also by electrocardiography because some of the patients complained of precordial

distress. Twenty-seven patients were studied by serial electrocardiograms. All but 2 showed definite changes on a maximal dose of phenytoin sodium for each patient. Thirteen, or approximately 50 per cent, showed prolongation of the PR interval of from two hundredths to four hundredths second. Twenty-one, or 78 per cent, showed a decrease in the amplitude of the T wave. In 3 cases there were P wave changes and in 1 case there was a significant alteration of the QRS complex. In all cases, after the drug was discontinued, the electrocardiographic pattern returned toward the normal for each patient. For example, in 1 patient an electrocardiogram taken six weeks after the beginning of treatment showed evidence of a heart block. This patient complained of precordial oppression. Successive electrocardiograms showed an increase in the PR interval and he continued to complain of precordial distress.

Phenytoin sodium was discontinued and the electrocardiograph was normal after a few months. Seven more patients not studied serially showed on the electrocardiograph a prolongation of the PR interval. One patient had edema of the legs.

The report by Williamson¹² of cardiac involvement as a result of treatment with phenytoin sodium is relevant in connection with the electrocardiographic changes that we have found. Three of his patients who had no history of cardiac or renal disease did have changes in the cardiac rate during the time that other toxic signs were present. One patient aged 20 had a simple bradycardia of 52 beats a minute three months after beginning treatment. Another, aged 58, had a bradycardia of 44 beats a minute with very frequent ventricular extrasystoles five weeks after starting treatment with phenytoin sodium. The patient complained of weakness, breathlessness and swelling of the ankles and showed cardiac dilatation, inversion of the T wave and clinical signs of cardiac insufficiency. The third patient had paroxysmal tachycardia which may merely have been coincidental and not due to treatment.

The other side effects due to phenytoin sodium as given in the table have at one time or another been reported by others, as mentioned in the survey of the literature. Although nausea and vomiting was quite frequent and may have been due to gastric irritability caused by the drug, the toxic effects as observed in 1 case simulating an acute abdominal condition is a more serious complication. The patient was a girl aged 19 who was given phenytoin sodium overlapping and substituting phenobarbital. When the dose of phenytoin sodium reached 0.6 Gm. a day a generalized weakness, severe abdominal pain, nausea and vomiting developed. There was no fever and the leukocyte count was normal. Phenytoin sodium was discontinued for a week and the symptoms disappeared. When treatment with phenytoin sodium was resumed the patient experienced the same symptoms within a week. She again recovered when phenytoin sodium was discontinued. When treatment with phenytoin sodium was begun a third time and she again had severe gastrointestinal symptoms she refused to take any more of the drug.

The loss of weight mentioned by others was also observed in some of our cases. The weight loss ranged from 1 to 22 pounds (450 Gm. to 9.1 Kg.). Fourteen patients lost weight, 11 gained and the others maintained the weight they had before treatment. Seventeen patients had a gingival hyperplasia, a condition first reported by Kimball.⁵

The only significant change noted in blood chemistry studies was an increase in the serum phosphatase. The phosphatase value after various periods of treatment ranged from 7.92 to 18.59 mg. per hundred cubic centimeters. The average value was 10.77. This is of interest in relation to hepatic involvement, since Mandelbaum and Kane¹⁰ reported a case in which there was enlargement of the liver and spleen with an increase in serum phosphatase.

Seven patients are still on treatment with phenytoin sodium. These patients were continued on treatment because phenytoin sodium definitely exerted favorable influences on their seizures. These patients also had side effects from phenytoin sodium but not sufficiently serious to indicate cessation of phenytoin sodium since the side effects were offset by the remissions caused by phenytoin sodium. These patients had the complications mentioned in the table, but at the present time, more than two years after treatment, they are for the most part free of them.

Of the 7 patients still on treatment with phenytoin sodium, 6 have had remissions from seizures of from ten to seventeen months and 1 is free from seizures for periods of about two months. Previously these patients had not responded favorably to bromides, to phenobarbital or to both.

SUMMARY

Forty-one patients with epilepsy were treated with phenytoin sodium according to the method of Merritt and Putnam. All the patients showed some side effect of the drug, ranging from apprehensiveness and irritability, present in 21 patients, to the development of an encephalopathy, in 4 patients. Side effects involved chiefly the nervous system and ataxia, vertigo, blurring of vision, nystagmus, tremors, insomnia and somnolence occurred. Status epilepticus, a paranoid confusional psychosis and encephalopathy were observed.

Of particular interest in relation to the cardiovascular system was electrocardiographic evidence of involvement of the heart. There were also toxic effects on the gastrointestinal system and the skin.

Clinical Notes, Suggestions and New Instruments

FAMILIAL HEREDITARY EDEMA

MILROY'S DISEASE

ROBERT L. STERN, M.D., CAMP CALLAN, CALIF.
1st Lieut., M. C., U. S. Army

The occurrence of familial hereditary edema, also known as Milroy's disease, hereditary trophedema and hereditary or congenital elephantiasis, is rare, particularly when a continued familial incidence can be demonstrated. Search of the literature reveals that fewer than fifty families with this hereditary syndrome have been reported. The following case is presented because such reports are rare and because of the studies, manifestations and improvement on treatment.

REPORT OF CASE

A. W. S., a white man, aged 25, unmarried, a selectee in the United States Army, was admitted to the Station Hospital, Camp Callan, California, Aug. 4, 1941 because of pain, swelling and mottled redness of the right foot. In civilian life he had been a painter. His home was in the Middle West. Since his induction in the army seven weeks prior to entering the hospital, he had been engaged in the usual training and drilling on the camp grounds. He stated that there had been some degree of pitting and swelling of the right foot as long as he could remember. His mother had told him that this had started when he was about a year old, or about the time he might have been expected to start walking. The condition has always been confined to the right foot. It has given him varying degrees of distress from none at all to the condition present on hospitalization. Symptoms have always been more severe during the summer months. Activity has little effect except that when he is on his feet a great deal the swelling is a little more noticeable. This clears somewhat when he is at rest with the foot elevated, but he is never without some slight degree of swelling. The foot has never been frostbitten or injured, nor has the skin ever blistered. He has never had an infection of the leg or abdomen. The patient has been a heavy smoker all his adult life, but there is no correlation between the amount of his smoking and the swelling of the foot.

The patient has had numerous and varied treatments in civilian life without relief of the condition. When the swelling is at its maximum or when acute episodes of redness and pain occur he experiences a sensation of shooting pain going up and down the bone between the ankle and the knee.

The patient was cooperative and intelligent. He stated that he had never had any serious illness and that he had had no venereal disease of any type. His only operation was a hernioplasty on the left side in 1930. His height was 65½ inches (168 cm.) and his weight 138 pounds (62.6 Kg.); his temperature peak was 100.6 F., pulse peak 100 on the day of entry and blood pressure 130 systolic and 85 diastolic. Physical examination was essentially negative except for premature baldness of the crown of the head, a well healed, freely movable inguinal scar on the left side and hot, red swelling of the right foot over the dorsum and sides from the ankle to but not including the toes, although the toes were slightly swollen. There were small petechial hemorrhages on the lateral aspect of the foot but nowhere else. The foot was moderately tender to deep pressure, and active motion was fair. There was no lymphangitis and no adenopathy.

Roentgen examination of the foot was reported by Lieutenant Sachs, roentgenologist, as follows: "The bones of the right ankle joint are within normal limits. Soft tissue studies of the ankle reveal a soft tissue swelling. There is no evidence of calcification of the soft tissue" (fig. 2).

Urinalysis was essentially negative; the blood Kahn reaction was negative. A blood count revealed the hemoglobin level

From the Coast Artillery Replacement Center, Station Hospital.

80 per cent, erythrocytes 3,850,000, leukocytes 9,050 with 76 per cent polymorphonuclear neutrophils. The blood sedimentation rate was 46 mm. (normal 5 to 10 mm.) and the blood uric acid content 3.5 mg. per hundred cubic centimeters.

Treatment consisting of administration of sulfathiazole and elevation of the foot was instituted and continued for one week. On the fourth day the temperature, which had remained at 99 to 100 F., returned to normal and continued at that level thereafter. At that time the redness of the foot had cleared and the pain had greatly diminished. On the fifth day of hospitalization the blood sedimentation rate was 30 mm., with the blood count approximately as before. The swelling of the foot persisted unchanged, however, and he was transferred to a medical ward. At the end of his second week in the hospital the cellulitis and the cutaneous irritation were completely cleared, but the swelling of the foot and ankle remained about the same. Examination of scrapings of the skin of the foot and between the toes failed to reveal any evidence of mycotic infection. Repeated urinalyses remained essentially negative. Blood counts were normal except for the persistent, moderately low erythrocyte and hemoglobin determinations. He continued to have occasional aching pain in the leg, but this was intermittent and slight, and he was ambulatory. Bed rest with elevation made little impression on the swelling, which was now firm but not brawny, pitted on pressure, was not tender and extended to a point about half way to the knee. The skin was now smooth, warm, of normal color and somewhat thickened. Both dorsalis pedis arteries pulsated normally.

On August 23, the twentieth hospital day, because of the persistent swelling and the important revelation of the foot swelling since infancy, familial hereditary edema was suspected and the patient questioned closely about hereditary factors. In regard to these, he was positive about the following: His maternal grandfather had the same type of swelling, confined to the left foot, with onset known to have occurred at the age of 16 years; his maternal great grandfather was said to have had the same condition, and the patient's mother has had unexplained swelling of both her legs since the age of 28. His grandfather had thirteen siblings, none of whom had a similar condition; his mother had three sisters, all of whom died in infancy, and two brothers who have no evidence of a similar condition. The patient had one brother and one sister who did not have a similar condition. The manifestations and history were deemed sufficient to establish a diagnosis of familial hereditary edema especially after further studies to exclude other conditions were made.

The sedimentation rate was now a normal 11 mm., the stool was found clear of pathogenic parasites and the total serum

Fig. 1.—Patient's legs just previous to mercupurin therapy, showing the swelling of the right foot.

protein was 6.9 mg. per hundred cubic centimeters. Roentgenograms of the chest, the pelvis and hip joints revealed a normal appearance. The blood pressure in the legs with the systolic determined by palpation of the first pulsation in the dorsalis pedis arteries was 168 in the left leg and 138 in the right leg. The venous pressure in the right leg was 10.5 cm.,

and at the same midcalf level in the left it was 9 cm. The circulation time from the midcalf of the left leg to the tongue, with the use of decholin, was ten seconds and of the right leg twenty seconds. The left leg-tongue time was determined first and, although a time lapse was allowed with the patient

Fig. 2.—Front and side view of the patient's right ankle and foot.

continuing at absolute rest, the difference in the circulation times was probably partially due to a dulled taste perception for the agent used.

On September 16, thirty-nine days after the redness and evidence of cellulitis had cleared, the comparative circumferences of the legs were, at the malleoli: right leg 12¼ inches (31.5 cm.), left 10 inches (25 cm.) at a level 3 inches (7.6 cm.) above the malleoli: right 9½ inches (24.5 cm.), left 8½ inches (22 cm.), the left leg having been, of course, of normal appearance throughout the period of observation. Above these levels the two legs were of the same circumference (fig. 1).

On September 17, the forty-fourth hospital day, because the swelling remained the same despite long periods of bed rest and because the patient still had intermittent aching of the leg, 2 cc. of mercupurin was administered intravenously. During twenty-four hours the patient had a fairly good diuresis, which it was impossible to measure accurately because the patient had to be out of the hospital part of the day, and his weight dropped from 136 to 133 pounds (61.7 to 60.3 Kg.). The right ankle and foot were definitely less swollen, the measurements now having decreased to 11 inches (28 cm.) in circumference at the malleoli and 8¾ inches (23 cm.) at a level 3 inches above the malleoli. With the reduction of the swelling of the foot, the intermittent distress in the foot cleared entirely.

Within the week he was discharged from the hospital in continued excellent general condition and was discharged from the army to his home by a Certificate of Disability Discharge. He was advised either to have mercupurin therapy whenever the leg caused distress or to try other suggested long term therapy under the supervision of a private physician. He reported by mail on October 13 that he continues to be in good general health and has no distress whatever in the leg, although some swelling persists.

SUMMARY AND CONCLUSIONS

1. A case of familial hereditary edema with a maternal family incidence in four generations has been reported because of the rarity of the condition described and because of the studies and observations made.

2. The case is further unusual because it is generally regarded that this type, the congenital as differentiated from the acquired,

which occurs later in life, does not present the acute pain and inflammatory episodes which this patient suffers.

3. The use of mercupurin to relieve the swelling gave complete relief from intermittent aching pain, which thereby is apparently demonstrated to be due to the swelling and not intrinsic with the syndrome.

PSITTACOSIS

HENRY ALICANDRI, M.D., BROOKLYN

Psittacosis, a highly communicable disease, has been transmitted to man by parrots, parakeets, love birds and rarer birds of the parrot family.

This communication is of interest because it presents an isolated case of psittacosis in which the only exposure to a bird was to the common pigeon; this possible source of infection warrants closer investigation.

REPORT OF CASE

L. M., a white man aged 35, born in the United States, a policeman, collapsed suddenly while on duty on Oct. 8, 1941. I saw him a few hours later, at which time he complained of fatigue, pain in the left lower portion of the chest extending from the axilla to the precordium, slight cough and blood tinged sputum. He also stated that he had had chills and fever and a "grippy" feeling for two or three days.

The past history showed no previous illness or operation. He was given sulfathiazole, and for the next six days the temperature varied from 100 to 103 F. The pulse rate was 70 to 80 and the heart sounds were distant and of poor quality.

On October 15 the pain in the chest became severe and the temperature rose to 104.5 F. The patient was flushed and the membranes were cyanotic; he was admitted to the Bay Ridge Hospital.

A roentgenogram made on admission revealed that the lung roots were clouded by central pneumonitis, and there was an exudative spread of this process into the lower lobe of the right lung. The heart appeared grossly enlarged to the left. The impression was that of influenzal pneumonia and mitral valvular disease. The heart sounds were weak at the apex, and the P wave in lead 2 was accentuated.

Examination of the blood on October 16 showed hemoglobin 96 per cent, erythrocytes 4,850,000, leukocytes 16,400, polymorphonuclear leukocytes 76 per cent, small lymphocytes 20 per cent, large mononuclear cells 3 per cent and eosinophils 1 per cent. On October 18 the blood showed hemoglobin 97 per cent, erythrocytes 4,950,000, leukocytes 17,650, polymorphonuclear leukocytes 70 per cent, small lymphocytes 22 per cent, large mononuclear cells 5 per cent and basophils 1 per cent. On October 20 the blood showed hemoglobin 84 per cent, erythrocytes 4,350,000, leukocytes 26,900, polymorphonuclear leukocytes 91 per cent, small lymphocytes 8 per cent and large mononuclear cells 1 per cent. The blood count on October 24 was hemoglobin 80 per cent, erythrocytes 4,480,000, leukocytes 9,800, polymorphonuclear leukocytes 78 per cent, small lymphocytes 11 per cent and large mononuclear cells 8 per cent. On October 27 the leukocytes numbered 12,500, polymorphonuclear leukocytes 6 per cent, small lymphocytes 24 per cent, large mononuclear cells 6 per cent and eosinophils 3 per cent.

Blood cultures showed no growth. Analysis of the urine revealed occasional casts and white blood cells but no albumin or sugar. The diazo test gave negative results. Pneumococci (of types I to XXXIII) were not found in the sputum. Mouse injection did not yield pneumococci or tubercle bacilli. The Wassermann reaction was negative. Agglutination tests for typhoid, paratyphoid and A and B brucellosis and typhus all gave negative results.

The temperature was spiky the first week, ranging from 100.5 to 104.5 F., and the pulse rate was comparatively slow, 80 to 120. The second week the curve was typhoidal, and the last two weeks the temperature curve was flat, at 99.5 F. Respirations were for the most part normal.

Another roentgen examination, on November 7, showed left ventricular hypertrophy. There was unresolved, diffuse, patchy pneumonitis.

Treatment was given with drugs of the sulfonamide series, circulatory supportive drugs and the use of an oxygen tent for three weeks.

In view of the clinical aspect of the patient, the roentgen data and the failure of response to treatment with sulfonamide derivatives, a tentative diagnosis of psittacosis was considered for investigation. A specimen of the patient's serum was sent to Dr. Karl Meyer of the George Williams Hooper Foundation in San Francisco, who reported on October 30 a strongly positive reaction (4 plus) for psittacosis (the antigen fixed in a dilution of 1:256).

Except for the occurrence of phlebitis of the right leg, recovery after the third week was uneventful, and the patient was discharged from the hospital on November 15. Subsequent roentgen and electrocardiographic examination was reported as giving normal results.

The only contact with birds known was with pigeons, some of which the New York City Department of Health obtained and forwarded to Dr. Karl Meyer in San Francisco.

SPONTANEOUS ELIMINATION OF A LIPOMA FROM THE SIGMOID FLEXURE

SYLVAN D. MANHEIM, M.D., AND HENRY PESKIN, M.D., NEW YORK

Benign tumors of the gastrointestinal tract are not frequent, and lipomas constitute but a small portion of those which do occur. Staemmler,¹ in a series of 17,000 consecutive post-mortem examinations, found only 9 lipomas, an incidence of 0.05 per cent. In a series of 3,924 consecutive autopsies at the Mayo Clinic, Comfort² found 20 intestinal lipomas, an incidence of 0.5 per cent. The discrepancy in these two series may have been due to the difference in size of the series or to the degree of care in searching for lipomas.

From time to time there have been reports in the literature of spontaneous elimination of gastrointestinal lipomas. In the sixty-five years from 1870 to 1935, 15 cases have been reported, 1 reported by Ninaus³ might not be properly included because an invagination of the intestine occurred and the tumor was expelled, together with the involved portion of intestine. In 1939 Odstrcil⁴ reported 3 more instances of spontaneously expelled lipomas, all of which occurred within a period of three years. In 1940 Backenstoe⁵ reported a case of submucous lipoma of the cecum spontaneously eliminated. To these 18 cases we wish to add the report of a case which was seen in the rectal clinic of the Mount Sinai Hospital. Before presenting this, however, several aspects of this phenomenon are worthy of note. Various theories have been offered in explanation of the mechanism of expulsion. One theory offered is that invagination of the affected area of the intestine results in necrosis with sequestration of the intussuscepted portion. Another is that the mucous membrane overlying the lipoma is torn at its base and the tumor slips through the mucosal defect. In our case, only a small portion of one end of the tumor was covered with mucous membrane, suggesting a possible thinning out and tearing of this membrane due either to direct trauma or to loss of blood supply as a result of pressure necrosis.

The symptoms have been varied. In some instances bleeding, usually intermittent, has been the chief or only symptom. In

others pain has been the patient's chief complaint. In several of the cases reported intestinal obstruction or intussusception caused the patient to seek medical assistance. In our case, mucopurulent discharge and intermittent diarrhea led to the tentative diagnosis of colitis by her family physician. There are also cases in which a roentgen examination suggested the presence of a neoplasm for which a laparotomy was performed

REPORT OF CASE

A white woman aged 47 was referred to the Rectal Clinic of the Mount Sinai Hospital by her family physician. She gave a history of intermittent diarrhea accompanied by blood and a mucopurulent discharge of many years' duration. In addition, she stated that she had been totally unable to have a bowel movement for the week prior to her initial visit. On rectal examination, after cleansing enemas had been given, the anus and rectum were found to be essentially normal. The sigmoidoscope was passed full length (25 cm) and blood was seen to be coming down from above this point. A roentgen examination of the colon with a barium enema was done, which was reported to show a filling defect of the midsigmoid region about 6 cm in length, suggesting a polypoid type of neoplasm with intussusception in this area. The remainder of the colon was normal (fig. 1).

Fig. 1.—Filling defect of midsigmoid

On the basis of these observations the patient was advised to enter the hospital for operation. She refused and instead returned to the clinic two weeks later to report that she had had severe abdominal cramps forty-eight hours previously. Accompanying these cramps she experienced an urge to defecate and, when her bowels moved, passed a large amount of blood and a tumor, which she retrieved and brought with her (fig. 2).

The pathologic report on the tumor was that it was a lipoma partially covered by necrotic sigmoidal mucosa showing acute inflammation. The specimen was an oval mass received in fixative and measured 6 by 4 by 4 cm. Three quarters of the mass was fairly soft; the remainder of the surface had a dirty greenish brown color and was somewhat more firm and granular.

Roentgen examination taken three weeks after the spontaneous elimination of the tumor revealed "a filling defect in the midsigmoid region about 3 cm in length" (fig. 3). Although the appearance was much less pronounced than at the previous examination, there was still evidence to suggest a small polypoid mass with intussusception. Another examination four weeks later presented the same picture. The patient has been seen at intervals over a period of five months; during this time she has been entirely symptom free.

The persistent roentgen signs suggest the possibility of another submucous lipoma being present, and because of that the patient will be kept under observation.

In reviewing the cases reported in the literature, we find that they were almost equally divided as to sex. The youngest patient was 16 years of age, the oldest was 87. The majority seemed to have been in the fifth or sixth decade. The exact location of these tumors was not always accurately determined, but the majority seemed to have originated in the colon. Some

Fig. 2.—Lipoma partially covered by necrotic sigmoid mucosa

of these tumors were merely 2 cm. in diameter, while that reported by Afetzou¹ was supposed to have been the size of a child's head. It should be noted here that the lipoma in the latter instance originated in the rectal ampulla, which may account for the large size that it attained without producing serious obstructive symptoms. Some of these lipomas were polypoid, others were sessile and in 2 instances the patient suffered from multiple lipomas, which were expelled over a period of weeks.

Fig. 3.—Appearance of sigmoid three weeks after elimination of lipoma

SUMMARY

A lipoma of the mid-sigmoid was spontaneously expelled with complete relief of symptoms. Lipomas constitute only a small percentage of the benign tumors of the intestinal tract, which in themselves are infrequent. Surgical intervention resulting from early diagnosis may account for the fact that only 20 instances of spontaneous expulsion of lipomas have been reported in the last seventy years.

336 Central Park West—41 West Ninety-Sixth Street.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

AUSTIN E. SMITH, M.D., Acting Secretary.

PROGESTERONE

The Committee on Revision of the U. S. P. XII has signified the intention of including progesterone, the corpus luteum hormone, in U. S. P. XII. The Council on Pharmacy and Chemistry has already published its preliminary report (J. A. M. A. 116:1523 [April 5] 1941) on progesterone, in which it was stated that the inclusion of this substance in N. N. R. was not warranted because of the lack of adequate evidence that progesterone therapy was conclusively established in any of the clinical indications for which it has been recommended. In its report the Council stated that further consideration of progesterone for acceptance would be deferred until additional scientific evidence becomes available, establishing definitely its usefulness.

In view of the discrepancy between the Council's view and that of the Committee on Revision of the U. S. P., the therapeutic indications for progesterone were again reviewed in the light of the latest available evidence. The Council, however, was unable to alter its opinion as to the status of progesterone therapy, although the potentialities of this substance were recognized. The Council, therefore, reaffirms its previous published opinion regarding the status of progesterone.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Acting Secretary.

CALCIUM GLUCONATE (See New and Nonofficial Remedies, 1941, p. 176).

The following dosage forms have been accepted.

Wafers Calcium Gluconate (Flavored)-Upjohn, 0.96 Gm (15 grains) Each wafer contains calcium gluconate, U. S. P., 15 grains with sugar, talc, dye and oil of wintergreen for flavoring.

Prepared by The Upjohn Company, Kalamazoo, Mich.

Ampoules Calcium Gluconate Solution 10% W/V Stabilized with Calcium D-Saccharate 1% W/V-Upjohn, 10 cc: Each ampul contains a sterile distilled water solution of calcium gluconate, U. S. P., 1.0 Gm, stabilized with calcium d-saccharate 0.1 Gm.

Prepared by The Upjohn Company, Kalamazoo, Mich.

CALCIUM D-SACCHARATE: The calcium d-saccharate used as a stabilizing agent in these solutions of calcium gluconate so stabilized complies with the following tests and standards.

Calcium d-saccharate occurs as a fine, white, odorless tasteless powder, which is stable in air. It is slightly soluble in water, ether, alcohol and chloroform. A saturated solution of calcium d-saccharate is neutral to litmus and possesses a pH of about 6.0.

Transfer about 0.1 Gm of calcium d-saccharate to a test tube, add 10 cc of water and 1 cc of diluted hydrochloric acid; the resultant solution is clear and colorless. To this solution add 5 cc of ammonium oxalate solution; a white precipitate appears, which is soluble in diluted hydrochloric acid.

Dissolve 0.5 Gm of calcium d-saccharate in 10 cc. of water and 2 cc of diluted hydrochloric acid, and boil the solution for two minutes. Cool, add 5 cc. of sodium carbonate solution, allow to stand for five minutes, dilute to 20 cc with distilled water and filter. Add 5 cc of the filtrate to 2 cc of alkaline cupric tartrate solution and boil for one minute; no red precipitate is formed (dextrose and sucrose).

One Gm of calcium d-saccharate shows no more chloride when tested with diluted nitric acid and silver nitrate solution than 1 cc of fiftieth-normal hydrochloric acid. A 2 Gm portion of calcium d-saccharate shows no more sulfate than corresponds to 1 cc of fiftieth-normal sulfuric acid when tested with diluted hydrochloric acid and barium chloride solution. Dissolve 1 Gm of calcium d-saccharate in 10 cc of distilled water and 3 cc. of diluted hydrochloric acid; add 10 cc. of hydrogen sulfide solution; no precipitate appears, and the color is not darker than a faint brown (heavy metals).

Transfer approximately 0.4 Gm. of calcium d-saccharate, dried over sulfuric acid and accurately weighed, to a 250 cc. beaker, and dissolve in 100 cc. of distilled water and 2 cc. of hydrochloric acid. Add an excess of ammonium oxalate solution, heat to boiling, and slowly neutralize with ammonia water, with stirring. Digest the mixture on a water bath for one hour, filter on hardened filter paper and wash thoroughly with warm distilled water. Puncture the filter paper, wash the precipitate into a beaker by means of a stream of hot distilled water, followed by 30 cc. of diluted (1:3) sulfuric acid. Heat the solution to 60 C. and titrate with tenth-normal potassium permanganate; the calcium oxide content is not less than 17.3 and not more than 17.7 per cent.

SODIUM r-LACTATE ONE-SIXTH MOLAR (See Revised Supplement to New and Nonofficial Remedies, 1941, p. 27).

The following brand has been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Sodium Lactate (Racemic) 1/6 Molar (1.87% W/V: 500 cc. and 1,000 cc. Upjohn Infusion Bottles. Each hundred cubic centimeters contains 1.87 Gm. of sodium r-lactate in sterile distilled water.

BLENDED OIL CONTAINING VITAMINS A AND D.—A mixture of fish and/or vegetable oils to which viosterol may be added. The vitamin A content is not less than 1,800 U. S. P. units per gram and the vitamin D content not less than 175 U. S. P. units per gram.

Actions and Uses—See article Vitamins A and D Preparations, N. N. R., 1941, page 562.

Dosage—See article Vitamins A and D Preparations, N. N. R., 1941, page 562.

Blended oil containing vitamins A and D occurs as a thin, liquid oil having a fishy but not rancid odor and a fishy taste. It is insoluble in water, slightly soluble in alcohol and soluble in chloroform, ether, benzene, ethyl acetate and carbon disulfide. The specific gravity is from 0.918 to 0.929 at 25 C. The refractive index is from 1.474 to 1.479 at 25 C.

A solution of one drop of blended oil containing vitamins A and D in 1 cc of chloroform, when shaken with one drop of sulfuric acid, acquires a blue color, gradually changing to purple. Fill a tall cylindrical tube of about 120 cc capacity with the oil and maintain at 0 C for five hours; the oil remains clear and fluid and deposits no solid material.

Dissolve 2 Gm, accurately weighed, of blended oil containing vitamins A and D in 30 cc. of a mixture of equal parts of ether and alcohol, previously neutralized to phenolphthalein, and boil gently under a reflux condenser for ten minutes. Cool and titrate the mixture with tenth normal sodium hydroxide to the production of a pink color which persists for thirty seconds, not more than 1 cc of tenth normal sodium hydroxide is required (free acid). The unsaponifiable matter in blended oil containing vitamins A and D is not more than 1.5 per cent when determined according to the method as given in the U. S. P. XI. The iodine value is not less than 145 nor more than 180. The saponification value is not less than 186 nor more than 202.

MEAD JOHNSON & CO., INC., EVANSVILLE, IND.

Mead's Blended Oil Containing Vitamins A and D: bottles 4 fluid ounces.

U. S. patent 1,680,818 (Aug. 14, 1928; expires 1945) and 1,861,136 (Aug. 9, 1934; expires 1951) under license of the Wisconsin Alumni Research Foundation.

Irradiated ergosterol, prepared by the method described under Mead's Viosterol in oil, is added to fish liver oil, sardine oil and maize oil, and the finished product is required to have a vitamin A potency of not less than 1,800 units (U. S. P.) per gram and not less than 175 units (U. S. P.) of vitamin D per gram.

DEXTROSE (See New and Nonofficial Remedies, 1941, p. 179).

The following additional dosage forms have been accepted:

HOSPITAL LIQUIDS, INC., CHICAGO.

Dextrose 20% (W/V) in Distilled Water in Filtrair Container: 500 cc, 1,000 cc. and 2,000 cc. bottles. Each hundred cubic centimeters contains dextrose-U. S. P. 20 Gm.

Dextrose 50% (W/V) in Distilled Water: 50 cc. and 100 cc vials. Each hundred cubic centimeters contains dextrose-U. S. P. 50 Gm.

Dextrose 2 1/2% (W/V) in Physiologic Sodium Chloride Solution in Filtrair Container: 500 cc, 1,000 cc. and 2,000 cc. bottles. Each hundred cubic centimeters contains dextrose-U. S. P. 2.5 Gm and sodium chloride-U. S. P. 0.9 Gm.

Dextrose 7 1/2% (W/V) in Physiologic Sodium Chloride Solution in Filtrair Container: 500 cc, 1,000 cc. and 2,000 cc. bottles. Each hundred cubic centimeters contains dextrose-U. S. P. 7.5 Gm. and sodium chloride-U. S. P. 0.9 Gm.

Dextrose 20% (W/V) in Physiologic Sodium Chloride Solution in Filtrair Container: 500 cc, 1,000 cc. and 2,000 cc. bottles. Each hundred cubic centimeters contains dextrose-U. S. P. 20 Gm. and sodium chloride-U. S. P. 0.9 Gm.

Dextrose 5% (W/V) in Isotonic Solution of Three Chlorides in Filtrair Containers: 500 cc., 1,000 cc. and 2,000 cc. bottles. Each hundred cubic centimeters contains dextrose-U. S. P. 5 Gm, sodium chloride-U. S. P. 0.7 Gm, potassium chloride-N. F. 0.03 Gm. and calcium chloride-U. S. P. 0.025 Gm.

Dextrose 10% (W/V) in Isotonic Solution of Three Chlorides in Filtrair Container: 500 cc., 1,000 cc. and 2,000 cc. bottles. Each hundred cubic centimeters contains dextrose-U. S. P. 10 Gm., sodium chloride-U. S. P. 0.7 Gm, potassium chloride-N. F. 0.03 Gm. and calcium chloride-U. S. P. 0.025 Gm.

SILVER NITRATE (See New and Nonofficial Remedies, 1941, p. 499).

The following dosage form has been accepted:

THE WM. S. MERRELL CO., CINCINNATI.

Solution Silver Nitrate 1% W/V: 0.5 cc. wax ampules.

ANTIPNEUMOCOCCIC SERUM, TYPE 1 (FROM RABBITS) (See New and Nonofficial Remedies, 1941, p. 447).

The following brand has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Antipneumococcic Serum (Rabbit), Type 1: Vials, 20,000 and 50,000 units. A refined and concentrated globulin solution of pneumococcus antibodies prepared by immunizing rabbits against virulent cultures of the type 1 pneumococcus. It contains 0.4 per cent phenol and 1-50,000 phenyl mercuric acetate as a preservative.

ANTIPNEUMOCOCCIC SERUM, TYPE 2 (FROM RABBITS) (See New and Nonofficial Remedies, 1941, p. 448).

The following brand has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Antipneumococcic Serum (Rabbit), Type 2: Vials, 20,000 and 50,000 units. A refined and concentrated globulin solution of pneumococcus antibodies prepared by immunizing rabbits against virulent cultures of the type 2 pneumococcus. It contains 0.4 per cent phenol and 1-50,000 phenyl mercuric acetate as a preservative.

ANTIPNEUMOCOCCIC SERUM, TYPE 3 (FROM RABBITS) (See New and Nonofficial Remedies, 1941, page 449).

The following brand has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Antipneumococcic Serum (Rabbit), Type 3: Vials, 20,000 and 50,000 units. Also available in vials containing 100,000 units. Each package contains a vial of normal rabbit serum (1:10 dilution) for the conjunctival test. A refined and concentrated globulin solution of pneumococcus antibodies prepared by immunizing rabbits against virulent cultures of the type 3 pneumococcus. It contains 0.4 per cent phenol and 1-50,000 phenyl mercuric acetate as a preservative.

ANTIPNEUMOCOCCIC SERUM, TYPE 4 (FROM RABBITS) (See Revised Supplement, 1941, page 30).

The following brand has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Antipneumococcic Serum (Rabbit), Type 4: Vials, 20,000 and 50,000 units. A refined and concentrated globulin solution of pneumococcus antibodies prepared by immunizing rabbits against virulent cultures of the type 4 pneumococcus. It contains 0.4 per cent phenol and 1-50,000 phenyl mercuric acetate as a preservative.

ANTIPNEUMOCOCCIC SERUM, TYPE 5 (FROM RABBITS) (See New and Nonofficial Remedies, 1941, page 449).

The following brand has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Antipneumococcic Serum (Rabbit), Type 5: Vials, 20,000 and 50,000 units. A refined and concentrated globulin solution of pneumococcus antibodies prepared by immunizing rabbits against virulent cultures of the type 5 pneumococcus. It contains 0.4 per cent phenol and 1-50,000 phenyl mercuric acetate as a preservative.

ANTIPNEUMOCOCCIC SERUM, TYPE 7 (FROM RABBITS) (See New and Nonofficial Remedies, 1941, page 450).

The following brand has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Antipneumococcic Serum (Rabbit), Type 7: Vials, 20,000 and 50,000 units. A refined and concentrated globulin solution of pneumococcus antibodies prepared by immunizing rabbits against virulent cultures of the type 7 pneumococcus. It contains 0.4 per cent phenol and 1-50,000 phenyl mercuric acetate as a preservative.

ANTIPNEUMOCOCCIC SERUM, TYPE 8 (FROM RABBITS) (See New and Nonofficial Remedies, 1941, page 451).

The following brand has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Antipneumococcic Serum (Rabbit), Type 8: Vials, 20,000 and 50,000 units. A refined and concentrated globulin solution of pneumococcus antibodies prepared by immunizing rabbits against virulent cultures of the type 8 pneumococcus. It contains 0.4 per cent phenol and 1-50,000 phenyl mercuric acetate as a preservative.

ANTIPNEUMOCOCCIC SERUM, TYPE 14 (FROM RABBITS) (See THE JOURNAL, Dec. 13, 1941, page 2073).

The following brand has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Antipneumococcic Serum (Rabbit), Type 14: Vials, 20,000 and 50,000 units. A refined and concentrated globulin solution of pneumococcus antibodies prepared by immunizing rabbits against virulent cultures of the type 14 pneumococcus. It contains 0.4 per cent phenol and 1-50,000 phenyl mercuric acetate as a preservative.

SOLUBLE IODOPHTHALEIN (See New and Nonofficial Remedies, 1941, p. 233).

Ampuls Iodeikon, 3.5 Gm.-Lakeside: Each ampul contains 3.5 Gm. of iodeikon (soluble iodophthalein).

Prepared by Lakeside Laboratories, Inc., Milwaukee.

VIOFORM-CIBA (See New and Nonofficial Remedies, 1941, p. 297).

The following additional dosage form has been accepted:

Tablets Vioform-Ciba, 250 mg.

SULFAPYRIDINE (See New and Nonofficial Remedies, 1941, p. 511).

The following dosage form has been accepted:

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Tablets Sulfapyridine: 0.5 Gm. (7½ grains).

MAGNESIUM TRISILICATE (See New and Nonofficial Remedies, 1941, p. 343).

The following dosage form has been accepted:

LAKESIDE LABORATORIES, INC., MILWAUKEE.

Tablets Magnesium Trisilicate: 0.49 Gm. (7½ grains).

AMNIOTIN (See New and Nonofficial Remedies, 1941, p. 375).

The following additional dosage forms have been accepted:

Amniotin Capsules, 10,000 International Units.

Amniotin in Corn Oil, 20 cc. vials, 2,000 International Units per cc.

Amniotin in Corn Oil, 10 cc. vials, 10,000 International Units per cc.

ASCORBIC ACID-U. S. P. (See New and Nonofficial Remedies, 1941, p. 557).

The following dosage form has been accepted:

Tablets Ascorbic Acid-SMACO, 100 mg.

Prepared by the S. M. A. Corporation, Chicago.

SUSPENSION OF EPINEPHRINE IN OIL, 1:500 (See New and Nonofficial Remedies, 1941, p. 255).

Epinephrine in Oil, 1:500-Lakeside.—A brand of suspension of epinephrine in oil, 1:500-N. N. R.

Manufactured by The Lakeside Laboratories, Inc., Milwaukee. No U. S. patent or trademark.

Ampuls Epinephrine in Oil, 1:500-Lakeside, 1 cc.: A suspension of 2 mg. powdered epinephrine crystals in 1 cc. of sesame oil.

DIGITALIS (See New and Nonofficial Remedies, 1941, p. 204).

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Tablets Digitalis: ¾ grain (½ U. S. P. unit) and 1½ grains (1 U. S. P. unit) (enteric coated). The tablets are first coated with a white shellac and then sugar-coated green.

AMINOPYRINE (See New and Nonofficial Remedies, 1941, p. 399).

The following dosage form has been accepted:

THE WM. S. MERRELL CO., CINCINNATI.

Tablets Aminopyrine: 0.324 Gm. (5 grains).

SATURDAY, APRIL 4, 1942

THE ATLANTIC CITY SESSION

Several Fellows of the American Medical Association have suggested that the Atlantic City session might be removed to the interior of the country because of the possibility of increased danger on the sea coast. To obtain an official expression of opinion on this point, the editor of THE JOURNAL consulted Robert P. Patterson, Under Secretary of War, in Washington. Mr. Patterson writes:

Dear Dr. Fishbein:

I have your letter of March 23 raising the question as to whether it would be advisable to move the convention of the American Medical Association away from Atlantic City.

I know of no valid reason why this convention should not be held in Atlantic City. The partial blackout of that city has been ordered to provide safer passage of ships which would be silhouetted against the bright lights of the city.

I want to take this occasion to express my appreciation and that of the War Department for the splendid work that the American Medical Association is doing and will continue to do to aid the Army in the recruitment of physicians who are so badly needed.

Robert P. Patterson,
Under Secretary of War.

The Atlantic City hotels report many reservations; several leading hotels are already completely reserved. The program is complete, including several special sessions devoted to military medical problems. The Convention Number, giving full details, is scheduled for May 2.

MODERN BREAD

For some two years medical and nutritional scientists have discussed the nutritional significance of bread, lawyers have argued about regulations pertaining to flour and bread, advertising copy writers have written about the new enriched bread. Consumers apparently have continued to pay scant attention to the important changes that have been made recently in this basic

food. The average American consumes each day about $6\frac{1}{4}$ ounces of white flour in various forms; to a large extent flour is used as white bread and other bakery products. This amount of flour will provide about one fourth of the average daily caloric requirements. The amount of white pan bakers' bread consumed daily is sufficient to provide each man, woman and child in the country with 70 Gm. of bread each day, or approximately two and one-third slices weighing 30 Gm. each. Nearly all this bread is consumed without special regard to its nutritional value.

Bread today is not the same as ordinary white bread of previous years. Now bakers use greater quantities of dried skim milk in the dough for all bread except Vienna style loaves. Rye bread and whole wheat bread also are ordinarily made without milk solids. If the skim milk solids are added at the rate of 6 pounds to each hundred pounds of flour (much of the white bread now is made with only half as much) the resulting white bread has almost the same riboflavin content as whole wheat bread made with water. Such milk bread has appreciably more calcium, from the milk solids, than the wheat grain. The milk proteins also represent a significant contribution. Nevertheless, ordinary white bread, while it is a good food, does not supply as much dietetic value as nutritional experts consider a bread should provide.

In a monograph entitled "Modern Bread from the Viewpoint of Nutrition," Sherman and Pearson¹ discuss the fundamental characteristics of bread as food, the individual nutritional essentials of importance in wheat and in bread, and the progress that has been made toward improving bread. Whole wheat, say Sherman and Pearson, is an excellent source of iron, but about four fifths of the iron of whole wheat is rejected in the milling of ordinary white flour. The grain is a good source of the vitamins of the B complex, especially of thiamine, but thiamine and riboflavin and nicotinic acid are largely lost in the milling of white flour. Recent work by Elvehjem, as yet unpublished, indicates that other factors of the vitamin B complex are rather uniformly distributed throughout the grain so that white flour and whole wheat flour are both fair sources of pantothenic acid and pyridoxine. Enriched bread will have a considerable portion of the original thiamine restored, and some of the nicotinic acid.

There are three principal methods by which a baker can make enriched bread. One is by using enriched flour instead of ordinary flour. Another is by incorporating in the dough a concentrate of either milling products of wheat or an artificial preparation of the desired composition. Another method is to use a yeast

1. Sherman, H. C., and Pearson, C. S.: *Modern Bread from the Viewpoint of Nutrition*, New York, Macmillan Company, 1942

which has enhanced nutritive value. By any of these methods a white bread indistinguishable from ordinary white bread is obtained or it may have a light creamy color or yellowish brown. Nutritionally it is far superior to ordinary bread. Enriched bread does not have some of the disadvantages of whole wheat bread, although the latter is recognized as a meritorious product. The disadvantages overcome are the higher amount of roughage in whole wheat bread, which some persons are not able to tolerate, and the difficulty of keeping whole wheat flour.

The vast majority of Americans prefer white bread to dark bread. Enriched bread can be made to satisfy this wish without much sacrifice of nutritive values that are associated with the darker breads. In England nutritionally improved bread is made with flour of 85 per cent extraction,² meaning that only 15 per cent of the wheat grain is not incorporated in the flour. Ordinary white flour represents about 70 per cent extraction of the grain. The British bread is fortified with calcium salts, which is an optional ingredient of American enriched bread.

Each slice of either white, enriched or whole wheat bread will supply roughly about 15 Gm. of carbohydrate and 3 Gm. of protein, yielding about 70 calories. A slice of white bread will have about 0.02 mg. of thiamine, a slice of enriched bread will have about 0.07 mg., and a slice of whole wheat bread will have about 0.10 mg. of thiamine. Of nicotinic acid the amounts would be in each slice 0.2, 0.4 and 0.7 mg., the enriched bread again being intermediate in value between that of white bread and that of whole wheat bread. The iron content of the three products will be 0.1, 0.3 and 0.8 mg. respectively for a slice of white, enriched or whole wheat bread. These figures are based on the assumption that the enriched bread is of the minimum value that has been developed for this product. The tendency is definitely to aim toward the minimum rather than the maximum, which is four times more, or some intermediate value. Final standards for enriched bread have not yet been formulated by the Food and Drug Administration. It has been decided, however, that riboflavin, for which standards have been established for enriched flour, will not be required as an ingredient of that product until after the middle of the year 1942.

Within recent years all the changes and improvements in this product have been toward the improvement of its nutritive quality. In the development of enriched bread, bakers have been guided by leading scientists and medical investigators. Sherman and Pearson observe that enriched bread may now safely be utilized to supply as much as 40 per cent of the calories of the normal diet, provided the greater consumption of enriched bread is at the expense of less

nourishing foods. This is an important observation—bread is exceptional from the point of view of economy. More than ever before bread deserves to be called the staff of life. Consumers who buy white bread should demand enriched bread.

SYNTHESES IN THE INTESTINE

The manifold functions of the intestine create many practical problems for the physician. Not the least of these is the fact that the intestine is not sterile; probably the first swallow of food of the newborn infects the tract. The observation that the clotting time of the blood is reestablished at the normal level ordinarily within a week indicates that the intestinal bacterial activity involved in the synthesis of vitamin K is active at that time. Through this symbiotic activity, no doubt, the organism as a whole reaps benefits of various kinds from the biochemical reactions in the intestine. Vigorous support for this thesis has been adduced by some recent observations of synthetic activity in ruminants.

Although micro-organisms can flourish on nutrient mediums whose nitrogen is provided by such simple organic compounds as asparagin, succinamide and urea, only amino acid nitrogen, either as such or in the form of protein, will suffice to promote nutritive well being in the mammal. Nevertheless, in cattle and sheep, nitrogen balance and growth can be promoted when urea provides the major part of the nitrogen. Even the nitrogen of ammonium bicarbonate is utilized.¹ In recent investigations Harris and Mitchell² have demonstrated that urea added to a basal low protein ration not only decreases the loss of body protein of adult sheep but also improves the appetite and the digestibility of the other constituents of the diet. Furthermore, in studies on growing lambs it was shown that nearly normal growth is afforded by the nitrogen of the urea and that the increments of tissue growth are normal in chemical composition. Do these experimental results indicate that the ruminant has a strikingly different requirement for nitrogenous compounds than do man and the carnivora? The evidence indicates that the bacteria in the multiple pouched stomach of these types, utilizing the simple nitrogenous compounds provided in the experimental ration, synthesize their own cell protein and that this bacterial protein then becomes available for the nutrition of the host.

Synthetic activity of intestinal bacteria has been demonstrated in other directions. In a series of studies³

Biol. & Med.* 45:769 (Dec.) 1940; 47:90 (May) 1941. Hunt, C. H.; Kiek, C. H.; Ruccougus, E. W.; Bethke, R. M.; Schalk, A. F., and Gerlaugh, Paul: *J. Nutrition* 21:85 (Jan.) 1941.

2. Specifications for National Flour, *Nature* 147:665 (May 31) 1941.

on rumen contents of sheep and cattle secured either after slaughter or by means of a permanent fistula it has been demonstrated that the bacteria in the intestine are able to synthesize thiamine, riboflavin, pyridoxine, pantothenic acid and nicotinic acid as well as vitamin K. This formation of vitamins by intestinal bacteria, which occurred on natural feeds and on experimental rations, can be considered a more or less significant source of these indispensable factors to these animals.

Doubtless similar reactions take place in the human intestine, though the magnitude is too limited to be of practical significance. Nevertheless, such studies suggest that products of bacterial activity may play a part in instituting more favorable conditions in the intestine in man, such as follow implantation of *Bacillus acidophilus*. They may even play a part in immunity.

Current Comment

IMMUNIZATION IS 1942 MAY DAY OBJECTIVE

By authorization of an act of Congress, the President of the United States annually proclaims May Day, May 1, as Child Health Day. Usually special attention is given to the health of infants and children with special reference to preventive measures such as well baby supervision, immunization against communicable diseases, protection of the milk supply and water supply, and corrective measures relating to so-called physical defects. This year May Day is to have a special objective. The migration of populations as a result of defense and war industry, and the building of cantonments with consequent mushroom growth in surrounding communities, plus the necessity for being prepared for possible evacuation has emphasized the danger of epidemics of communicable diseases. The United States Children's Bureau, which is responsible for the May Day celebration, recommends that a major effort be made to secure at once the immunization of all children over 9 months of age against the two diseases for which established methods of immunization are available: smallpox and diphtheria. Instead of waiting for May Day, the Children's Bureau, under the Presidential proclamation, will call specifically for an immediate effort to immunize all children over 9 months of age and, as soon as possible after the ninth month, against these two diseases. Private physicians, public clinics, dispensaries and hospital outpatient departments are urged to make every effort to have these immunizations performed in all children touched by their respective services. This should be achieved before May 1 as a contribution to the health of the nation's children and as a wise precaution against possible epidemics which might go far to disrupt or slow war production or the training of soldiers. These diseases might spread from foci near camps and war industries into the industrial

populations and the military and naval forces themselves. Adults, especially those not previously immunized against diphtheria, may be susceptible to these diseases, especially if they come from remote rural areas. In *Hygeia* in March there were published special articles on diphtheria immunization and smallpox vaccination, and many thousands of reprints are being distributed by health departments in various states. Although not specifically included in the May Day objective, immunization against typhoid, tetanus, whooping cough and scarlet fever may also be performed when indicated in the judgment of the physician.

"DOCTORS AT WORK" AUDIENCE CHECK

Radio program audiences can be checked in several ways. Audience mail response is one of the quickest and easiest, and, if interpreted conservatively, most satisfactory. Few programs receive audience mail in appreciable amount unless some effort is made to cause listeners to write. "Doctors at Work," the radio program of the American Medical Association and the National Broadcasting Company, now in its second season, has no product to offer for sale. To ascertain how many listeners would respond to an offer to send them printed material in the field of health education, Doctors at Work in January 1941 offered a list of first aid supplies and how to use them, suitable for pasting inside the medicine cabinet door. This was announced on two successive programs, only one short reference being made at the end of each broadcast. The offer brought 8,200 letters and cards requesting the list. In April, just as the touring season began to open, another test was made, this time of a chart and table of highway health and accident safeguards. This offer, made in the same way as that in January, brought only 2,800 replies. In 1940-1941, Doctors at Work enjoyed the advantage of a favorable evening hour, 10:30 p. m. eastern time, Wednesdays. In the 1941-1942 season a suitable evening hour was not available, and the series was opened on December 1 at 5:30 p. m. eastern time, Saturdays. In a few weeks this time was switched to 5 o'clock eastern time, where it has since remained. In March 1942 an offer was made to listeners to send them a check list of fifty factors which contribute to the health of home and family, an instrument by which their own health practices could be evaluated. The offer was made in the usual fashion, one short reference on two successive broadcasts. The number of replies exceeded 8,600 (8,650, March 31). It is, of course, impossible to estimate accurately the actual number of listeners from such responses. However, only small percentages of listeners respond even to an offer of more or less tangible objects, such as usable samples. The responses to audience mail tests here reported are considered in radio circles highly satisfactory for a noncommercial program. Doctors at Work has a large following of faithful listeners. This following is nationwide; every state is represented in this response, as are Canadian listeners.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

CIVIL SERVICE COMMISSION RECOMMENDS ENROLMENT

In the past, the U. S. Civil Service Commission, in furnishing to federal agencies the names of physicians, dentists and veterinarians who had qualified in civil service examinations, has found that the making of appointments has been retarded by an excessive proportion of declinations from those eligible when appointment was offered. Persons who were available for federal medical positions when the examination was held were no longer available for such appointment when their names were reached on the commission's register of the eligible.

The present war emergency demands promptness in filling vacancies in various governmental agencies, and the determination of immediate availability of applicants for civil service employment early in the examining process has become of increasing importance. The U. S. Civil Service Commission, therefore, is recommending that all physicians, dentists and veterinarians who are interested in civil service employment enrol with the Procurement and Assignment service, and that they definitely indicate on the questionnaire the governmental agency in which they desire employment.

The agencies which employ the largest number of physicians and dentists under civil service regulations are the Veterans Administration, the Indian Service (Department of the Interior), the Public Health Service

(Federal Security Agency), the Panama Canal and the Children's Bureau (Department of Labor).

At present there is a shortage of fully qualified physicians who are available for employment in the federal civil service, and it is important that more of the physicians who are not available or qualified for commissions in the Army, Navy or Public Health Service offer their services during the war emergency in a civilian capacity in federal agencies having civilian medical services.

In accordance with an executive order, "war service" appointments are now being made in the various governmental agencies. Such appointments are for the duration of the war and for six months thereafter. The physical requirements for war service appointments are liberal. Appointments are being made of physicians who qualify for the associate or full grade medical officer under the U. S. Civil Service Commission's current open continuous examination. To qualify as the associate or full grade medical officer, physicians must have graduated from an approved medical school subsequent to May 1, 1920.

The U. S. Civil Service Commission will utilize the information obtained by the Procurement and Assignment Service's enrolment program in recruiting physicians, dentists and veterinarians to fill the needs of the civilian medical, dental and veterinarian services of governmental agencies.

VERNE K. HARVEY, M.D., Washington, D. C.
Medical Director, U. S. Civil Service Commission.

FEDERAL CIVIL SERVICE

VERNE K. HARVEY, M.D.,
Washington, D. C.

The U. S. Civil Service Commission, responsible for the recruitment of medical and other personnel for positions in the federal government which are subject to civil service law, joins other federal agencies in urging physicians, dentists and veterinarians to enroll with the Procurement and Assignment Service when the enrolment forms are mailed in the very near future.

The commission emphasizes that the lists compiled through the enrolment will be utilized in filling not only positions in the commissioned medical services of the War and Navy departments and the Public Health Service but positions in civilian medical services of federal agencies as well.

The commission is continuing to recruit medical officers by the direct method of announcing and publicizing examinations for medical positions. An examination for medical officer, for example, has been announced on a "continuously open" basis. But the demands of the federal agencies, rapidly expanding as a result of the national emergency, cannot be met by this method alone.

As a supplementary measure, therefore, the commission will call for the names of qualified persons appearing on lists of the

Procurement and Assignment Service who have indicated in their enrolment forms that they are interested in serving in a civilian capacity in one of the federal agencies. The Procurement and Assignment Service will give due consideration to whatever other requests for personnel are pending and then furnish to the commission the names of available physicians, dentists or veterinarians. The Procurement and Assignment Service would select the names of (a) persons who had indicated in their enrolment forms that they were primarily interested in positions in the federal civil service and (b) persons who had expressed a preference for positions in the commissioned service of the War or Navy Department or the Public Health Service but were not qualified therefor. In either instance, only those persons who met the requirements of the commission's examination would be certified to an agency for appointment.

ENROLMENT

Physicians, dentists and veterinarians are requested to indicate in spaces provided on the enrolment form in which of the following classes of medical service they prefer to assist: (1) military (commissioned services of the War and Navy departments and the Public Health Service), (2) governmental (civil service), (3) industrial and (4) civil (nongovernmental). They should indicate their first, second, third and fourth preferences.

Under the heading "U. S. Civil Service Agencies" is a list of some of the federal agencies which maintain civilian medical

services. Those who are interested in employment in the federal civil service should indicate the agency in which they prefer to serve.

PROCEDURE IN MAKING RECOMMENDATIONS

In recognition of the Procurement and Assignment Service's role as the central agency coordinating the distribution of medical personnel, the Civil Service Commission will proceed as follows when applications are received in response to announcement of civil service examinations for physicians, dentists and veterinarians:

1. The names of those applicants who have received an eligible rating will be submitted to the Procurement and Assignment Service, with the view of determining whether or not such applicants are essential in their present positions and localities.

4. The names of those persons who have been designated by the Procurement and Assignment Service as being essential in their present positions and localities will not be certified, and such persons will be notified by the United States Civil Service Commission that they cannot be certified in view of the action taken by the Procurement and Assignment Service.

3. The names of those persons who have been designated as available will be certified as candidates to fill the personnel needs of the various government agencies under civil service rules and regulations.

POSITIONS NOW OPEN IN CIVIL SERVICE

Under an executive order which became effective March 16, 1942 appointments to positions in the federal civil service (those positions in the federal executive civil service which are subject to the Civil Service Act) are placed on a "war service" basis. Appointments are made with the understanding that, provided satisfactory service is rendered, tenure will be for the duration of war and for six months thereafter. Probationary, or "permanent," appointments have been discontinued "for the duration."

Civil service examinations are now open for associate medical officer, \$3,200 a year; medical officer, \$3,800, and senior medical officer, \$4,600. No written test is required. Determination as to whether an applicant is eligible or ineligible for appointment is made on the basis of his education and experience. Applications are considered for any of fifteen optional branches of medical science. Full information regarding the medical officer examinations is set forth in a printed announcement which may be consulted at any first or second class post office. Copies may be obtained by writing to the U. S. Civil Service Commission, Washington, D. C.

A diversified field is open to the physician who elects to assist in the civilian medical services of the federal government during the emergency. The field encompasses virtually every phase of medical activity, ranging from rural practice to the most highly specialized activities.

THE INDIAN SERVICE

Not all civil service physicians are employed in large government hospitals. Many—for example, those employed in the Indian Service—are engaged in the general practice of medicine. The Indian Service maintains general hospitals and sanatoriums ranging from fifty to two hundred and fifty beds. Very active outpatient departments are connected with these hospitals. The physicians make home calls and field trips, conduct school examinations and administer general public health measures among the Indians.

PANAMA CANAL ZONE

Physicians who are interested in tropical diseases receive excellent opportunities to study that subject in the Canal Zone. Civil service physicians in the Canal Zone are employed primarily in dispensary and quarantine work. The dispensary work consists of general practice involving the attendance of government employees and their families, and crews and passengers of vessels. Quarantine physicians are concerned with quarantine and immigration inspection of crews and passengers on incoming vessels.

VETERANS ADMINISTRATION—SPECIAL SERVICES

Large numbers of federal medical officers are engaged in the fields of general practice, tuberculosis, psychiatry, surgery and public health. The opportunity for research in these fields is excellent. The Veterans Administration operates a large tumor clinic at Hines, Ill., tuberculosis clinics at the tuberculosis hos-

pitals, and heart clinics at Mount Alto Hospital, Washington, D. C. At St. Elizabeths Hospital, Washington, D. C., fine opportunities for residencies and internships in neuropsychiatry are open to recent graduates of medical schools. This hospital is under the jurisdiction of the Federal Security Agency.

FOOD AND DRUG ADMINISTRATION

Medical officers in the Food and Drug Administration (Federal Security Agency) are engaged in a critical review of the labelings of medicines in the light of their composition for the purpose of ascertaining whether or not the therapeutic representations are true or false as judged by a consensus of present day medical opinion. This work offers excellent opportunities to recent graduates of medical schools who have had, in addition to their regular medical education, experience in pharmacology.

CHILDREN'S BUREAU

The Child Hygiene Division of the Children's Bureau (Department of Labor) carries on research and investigation involving fundamental technical medical investigations of the mental and physical condition of children in relation to heredity, environment, nutrition and the efficacy of various methods of community health work. There are opportunities in this bureau for physicians with special training in pediatrics, obstetrics or public health procedure.

PUBLIC HEALTH SERVICE

Civilian medical officers in the Public Health Service (Federal Security Agency), as distinguished from medical officers in the commissioned force, are appointed as acting assistant surgeons and are usually detailed for local duty in the vicinity in which they reside. From time to time, however, there is opportunity for them to transfer elsewhere. They are employed in connection with practically all the activities of the Public Health Service. These include hospital and relief work, quarantine and immigration work, field investigations and epidemic control duty. The Public Health Service operates marine hospitals and relief stations throughout the United States. The beneficiaries in these hospitals and relief stations consist principally of merchant seamen, officers and enlisted men of the United States Coast Guard and civil employees of the federal government injured in line of duty.

The services of acting assistant surgeons are utilized at a large number of marine quarantine stations in connection with the inspection of vessels entering the United States from foreign ports and in connection with the medical examination of aliens entering this country. Acting assistant surgeons conduct investigations pertaining to industrial hygiene, goiter, anthrax, influenza, malaria, pellagra, pneumonia, tuberculosis, typhoid, child hygiene and public health administration.

VETERANS ADMINISTRATION

The Veterans Administration employs more civil service physicians than any other government agency. The medical service of the Veterans Administration comprises regional offices, facilities and diagnostic centers. The term "facility" is applied to various types of field stations, including those which are hospitals only, those which may provide domiciliary care and hospitalization, others which are a combination of regional offices and hospitals, and still others which are a combination of regional offices and homes. Facilities may be primarily designed for general (medical and surgical) service or for tuberculosis or neuropsychiatric service. However, some have a mixed service which may be a combination of any of these.

New appointees are first sent to one of several selected facilities of the Veterans Administration, at which they are given a training course in medical subjects and in administration, as based on the Regulation and Procedure, the Manual for Medical Examiners, clinical bulletins and other instructional publications of the Veterans Administration. After passing an examination at the end of this preliminary training course, appointees are assigned at the same or another facility for ward and other duties pertaining to an associate physician. Physicians in the service must be available for transfer to any facility within the continental limits of the country as need for their service arises.

The diagnostic centers located at Washington, D. C., Hines, Ill., and San Francisco were established for intensive study and

observation of patients presenting diagnostic problems and have consultant staffs consisting of physicians of national reputation in their fields. The diagnostic center at Hines, Ill., has one of the largest and most modern tumor clinics in the world.

Small clinics for thorough diagnosis and treatment of malignant growths are located strategically in facilities in New York City, Washington, D. C., Atlanta, Ga., Portland, Ore., and Los Angeles.

In nine facilities, scattered throughout the country, centers have been created for special chest surgery.

The volume and variety of the medical activities of the Veterans Administration are approached by few if any other organization. Veterans of former wars constitute a public of approximately four and one-half million persons who are potentially entitled to treatment by the Veterans Administration. Continuous accretions to that total are made through discharges from service of disabled officers and enlisted men of the Army, Navy, Marine Corps and Coast Guard. The huge total of hospital beds is constantly in demand, and abundant clinical material is afforded in all fields of medicine save obstetrics and pediatrics. The proportions of outpatient activities are unprecedented: In the fiscal year ended June 30, 1941 a total of 1,111,589 physical examinations were made and 1,176,658 treatments were rendered in the outpatient service. It is not only the numerical proportions of this service that make it valuable but quite as much the peculiar advantage derived from the continuity of contact that is afforded. It is the usual experience of civilian clinics to have patients drop off before completion of study or treatment; but the reexaminations that are called for from time to time, for purposes of pension, disability, compensation, government insurance, treatment and so on insure follow-up of Veterans Administration beneficiaries through successive years. The evolution of conditions can thus be observed, errors in earlier diagnoses can be corrected, and treatment to meet present indications can be prescribed to advantage through these circumstances.

The Veterans Administration is committed to and maintains a high standard of medical treatment and care. Clinicopathologic conferences of hospital staffs are regularly held. Continuous attention is given to the introduction of new diagnostic and

treatment methods, and the laboratory and clinical equipment is of modern design. Postgraduate "refresher" courses, as well as postgraduate courses in the specialties, are arranged whenever necessary at several of the larger stations, and official leave may be granted for attendance at courses in other clinics and hospitals in the country.

Medical research is supervised by a specially trained physician of the staff of the medical director, and projects are entrusted to physicians having the basic special qualifications to conduct them or who show aptitude for research. The Cardiovascular Research Unit, at Washington, D. C., was organized, under the direction of a chief, to standardize concepts and practices in cardiology, use of the electrocardiograph and so on. The Tumor Research Unit at Hines, Ill., conducts clinical and experimental research into the cancer problem and has published numerous papers and monographs on technical phases of this work. The Neuropsychiatric Research Unit at Northport, L. I., N. Y., conducts clinical and laboratory research in connection with neuropsychiatric disabilities and is engaged in standardizing the diagnostic and therapeutic methods used in connection with the management of neuropsychiatric disabilities. The *Medical Bulletin* of the Veterans Administration, issued quarterly, provides opportunity for the publication of articles and case reports prepared by physicians of the service.

OTHER GOVERNMENT AGENCIES

To a lesser extent, medical officers are employed in various other government agencies. Two medical officers in the Government Printing Office are in charge of a small well equipped hospital in which employees who are injured or become ill while on duty are treated. The Bureau of Engraving and Printing requires the services of a physician for similar duty. The Census Bureau of the Department of Commerce employs physicians who engage in medical statistical study. In the Civil Service Commission in Washington, D. C., and in thirteen district offices a number of medical officers are engaged in medical activities pertaining to government employment. This activity is a combination of insurance, industrial and administrative medicine and affords young physicians a basic training in these fields which is unique in the United States.

HEALTH OF SELECTIVE SERVICE REGISTRANTS

LEONARD GEORGE ROWNTREE, M.D.

Colonel, M. C. U. S. Army; Chief, Medical Division,
Selective Service System

KENNETH H. MCGILL, A.B.

Chief, Research and Statistics Division
and

OLIVER HAROLD FOLK, B.S., M.A.

Captain, U. S. Army; Chief, Medical Statistics Section Research
and Statistics Division

Washington, D. C.

The Selective Service System is making a comprehensive analysis of the reports of physical examination of the registrants examined in accordance with the Selective Training and Service Act of 1940. Pending the complete analysis of these reports, a survey has been made of 19,923 medical records to provide an index to the physical fitness for military service of American youths between the ages of 21 and 36. This sample was drawn from each state in proportion to total registration and consists of a cross section of registrants examined prior to May 31, 1941.

RATE AND CAUSES OF REJECTION

This sample analysis of medical records and summary reports from the Selective Service local boards indicates that about 50 per cent of the approximately two million registrants who have been examined have been found

by local boards and by Army induction stations to be unqualified for general military service, physically, mentally and educationally. Of the approximately one million registrants who were not qualified for general military service, 900,000 were so classified because of lack of physical and mental qualifications and the remaining 100,000 because of lack of educational qualifications. The minimum educational requirement for a registrant to be inducted into the Army is the ability to read and write the English language as well as a student who has satisfactorily completed the fourth grade in an American grammar school. More than one half, 470,000, of the 900,000 rejected for physical and mental reasons were qualified for limited military service only, and 430,000 were totally disqualified for any military service.

Based on the major pathologic condition recorded or the principal cause of rejection by Selective Service local boards and by Army induction stations, dental deficiencies accounted for an estimated 188,000, or 20.9 per cent of the 900,000 registrants not qualified for general military service. Defects of the eyes and impaired vision constituted an estimated 123,000, or 13.7 per cent.

The estimated number of registrants found to be unqualified for general military service by other defects or diseases are set forth in table 1 and chart 1. The table also shows a breakdown of the number who were found to be available for limited military service by Selective Service local boards and those who were dis-

qualified for any military service. Hernias, venereal diseases and defects and diseases of the teeth, eyes and feet were the principal types that, while disqualifying for general military service, still would permit the individual registrant to perform limited military service. Diseases and defects of the cardiovascular system seem to be the principal causes in total disqualifications for any military service.

Included in the miscellaneous group were diseases and defects of the mouth and gums, nose, throat, kidneys and urinary system, abdomen, genitalia and skin together with hemorrhoids, varicose veins, tumors, and infectious and parasitic diseases.

INCIDENCE OF DEFECTS

The major pathologic condition indicates the reason why registrants were rejected but does not afford an

number of defects tabulated. Dental defects, which were the largest cause of rejection for military service, comprised 10.3 per cent of the diseases and defects. In addition to nondisqualifying defects, a large proportion of the disqualifying defects are minor as far as health conditions are concerned.

Many defects are a cause for rejection for service in the Army but in no way hinder the performance of many civilian occupations.

AGE, HEIGHT AND WEIGHT OF REGISTRANTS

As the reports of physical examination considered in this survey were for men examined prior to May 31, 1941, registrants between the ages of 21 and 36 were included as well as a small number of men between the ages of 18 and 21 who volunteered through the Selective Service System for military service. Two

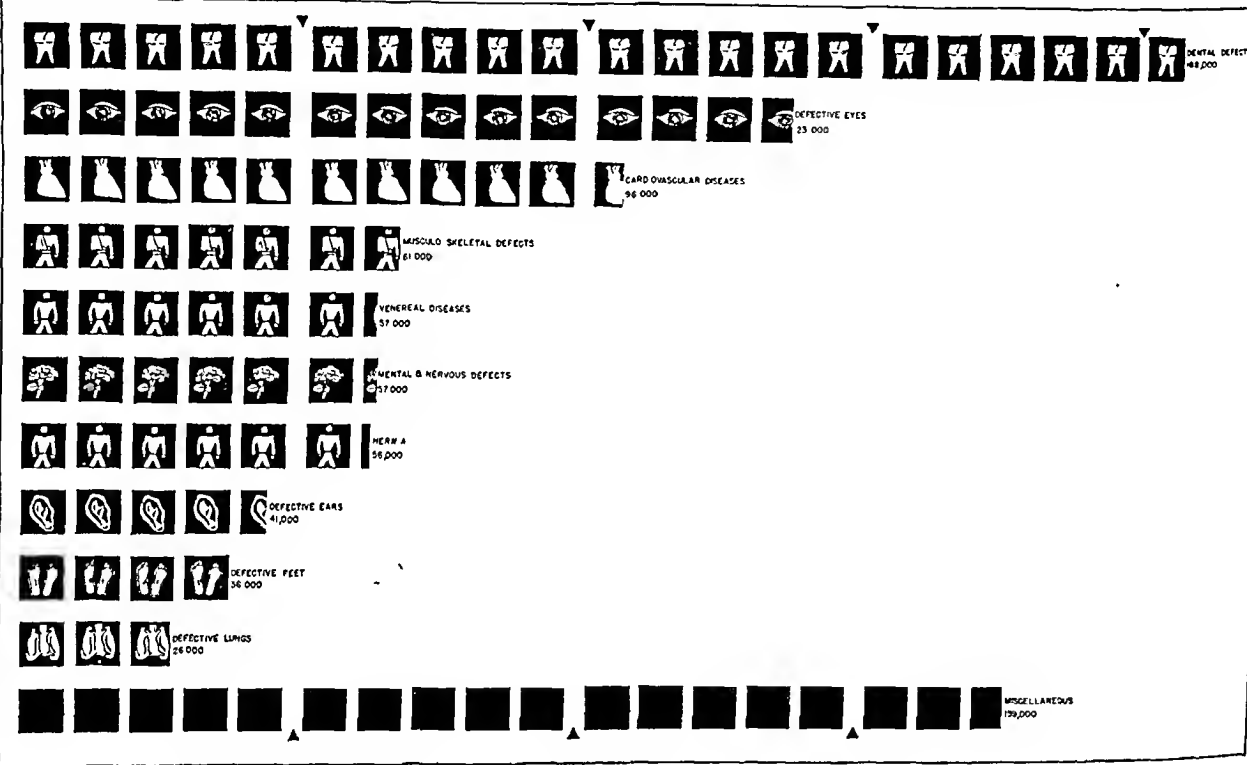

Chart 1.—Estimated number of selectees rejected. Each symbol represents 1 per cent of the 900,000 rejected.

accurate index as to the incidence and prevalence of diseases and defects among registrants. In this study a maximum of three defects was recorded. A total of 27,031 defects were tabulated from the 19,923 reports of physical examination, an average of one and four-tenths defects per registrant examined. No defects were recorded, however, for 5,741 registrants, or 29 per cent, of the total number examined. Of the total of 27,031 defects, one or more were recorded for each of 14,182 registrants, an average of one and nine-tenths defects per registrant with defects. Two defects were recorded for each of 8,433 registrants and three defects for 4,416 registrants.

In table 2 there is a list of the defects or diseases tabulated by broad classifications with the rate per thousand registrants examined. This tabulation includes defects which do not disqualify as well as defects which do disqualify for general military service. Defective feet accounted for the largest number of disease and defects recorded for any single organ, section or system of the body and comprised 10.7 per cent of the total

thirds of the registrants examined by local boards were between the ages of 21 and 27, inclusive. Registrants between the ages of 28 and 36, inclusive, accounted for 31.3 per cent of the total number examined, and the number of volunteers between the ages of 18 and 21 accounted for 2.1 per cent of the total registrants examined.

The rate of rejection for registrants between the ages of 31 and 36 was nearly twice as great as that of registrants between the ages of 21 and 25, inclusive. Sixty-one per cent of the registrants between the ages of 31 and 36 were unacceptable for general military service as compared to 45 per cent between the ages of 26 and 30 and 34 per cent between the ages of 21 and 25. The percentage who were qualified for general military service varied from 70.5 for registrants 21 years old to 29.9 for registrants who were 36 years old at the time of physical examination.

The relationship that exists between the registrant's age and availability for general military service is shown in table 3 and chart 2.

The average height of registrants examined was 67½ inches (171 cm.), the average weight was 150 pounds (68 Kg.) and the average chest measurement in forced expiration was 33¼ inches (86 cm.). The average height of registrants qualified for general military service was 68½ inches (173 cm.) and the average weight was 152 pounds (69 Kg.). The height of registrants examined varied from 54 inches (137 cm.) to 88 inches (223.5 cm.), and 98.3 per cent of the registrants were between 60 inches (152 cm.) and 78 inches (198 cm.) in height, which are the minimal and maximal heights, respectively, for acceptance by the Army.

the registrants examined were from urban communities. The rate of rejection for registrants from urban areas was 42.4 per cent as compared to 38.1 per cent for rural areas.

The United States and its territories were the place of birth of 97.3 per cent of the registrants examined, most of the others having been born in Canada, British Isles and Europe. The rate of rejections for native born registrants was 40.9 per cent as compared to 45.6 per cent for registrants who were born outside the United States and its territories.

This finding perhaps, can be accounted for by the differences in age groups.

Chart 2.—Classification for military service in relation to age.

Registrants varied in weight from 85 pounds (38.6 Kg.) to 385 pounds (175 Kg.), and 93 per cent were between 100 pounds (45.4 Kg.) and 190 pounds (86 Kg.). The minimum weight for admittance into the Army for registrants 60 inches (152 cm.) tall is 105 pounds (47.6 Kg.), and the standard weight for a registrant 78 inches (198 cm.) tall is 184 pounds (83.5 Kg.).

RACE, URBAN-RURAL RESIDENCE AND PLACE OF BIRTH

The ratio of Negro registrants to the total number examined was approximately the same as the ratio of Negroes to the total population, 11 per cent. Registrants of other races, which accounted for less than 1 per cent of the total number examined, were mostly Chinese, Japanese and Indians. The rate of rejection for Negro registrants was 42.6 per cent as compared to 40.8 per cent for white registrants. Two thirds of

OCCUPATION

About one seventh of all registrants examined were unemployed at the time of examination. The largest group of employed registrants physically examined were operatives and kindred workers, which comprised about 20 per cent. Most numerous among operatives and kindred workers were chauffeurs, truck drivers, delivery men, weavers, knitters, spinners, assemblers and operators of lathes, drill presses and other machines. Farmers and farm laborers, the second largest employed group, accounted for 14 per cent of the total number examined. Craftsmen and foremen, which accounted for 8 per cent of all registrants examined, were mostly carpenters, cabinet makers, pattern makers, mechanics, repairmen, machinists, millwrights, tool makers, painters, paper hangers and printers. Approximately 1 per cent of the registrants examined were students. The occupations of the registrants examined are shown by broad classifications in table 4.

COMMENT

The information and data contained herein are the best available as to the health of a part of the United States male population. While these data indicate that approximately one half of the registrants being

for any military service in the United States Army evidence health conditions which would be acceptable for military duty in any army in continental Europe. Registrants are not physically examined who are found by Selective Service local boards to be essential to the national health, safety and welfare, such as those having community responsibilities to dependents or holding essential jobs

In the World War approximately 64 per cent of the 3,208,446 registrants examined between Dec. 15, 1917 and Sept. 11, 1918 were qualified for general military service.¹ An additional 17 per cent were qualified for limited military service, and 19 per cent were disqualified for any type of military service. This compares, not so unfavorably, with about 25 per cent being totally rejected for any type of military service at the present time when it is recalled that the examinations were made under considerably different conditions. During the World War period standards changed seven

TABLE 1.—Estimated Number of Registrants Found to be Unqualified for General Military Service Because of Physical and Mental Reasons, by Availability for Military Service and by Defect or Disease

Major Defect or Disease	Unqualified for General Military Service by Selective Service *			Unqualified for General Military Service by the Army †	Percentage of Estimated Total Unqualified for General Military Service

Infectious, parasitic and epidemic diseases	7	0.4
Other diseases and defects	974	48.9
Total	27,011	1,356.8

examined are found to be unfit for the performance of general military service, an additional one fourth are qualified for limited military service. Registrants classed as available for limited military service are not being inducted at the present time.

There seems to be little doubt that most of the registrants classed as available for limited military service and a substantial portion of those classed as disqualified

times. Registrants being examined during that period were mostly between the ages of 21 and 30 as compared to 21 and 36 in the data presented here.

Advances since 1918 in clinical medicine and diagnostic and laboratory procedures now present the means of eliminating more men from the service. For example, many registrants are being rejected because of latent syphilis that would not have been recognized in the World War. Chest roentgenograms are being used extensively. Many cases of tuberculosis are being found now that could not previously have been detected. By concentrated efforts, many of the men with borderline mental conditions are being rejected at the present time who would have been accepted into the Army in 1918. Also the psychology of the examiners themselves is entirely different than that which prevailed in the World War. Then it was necessary to secure men quickly, train them hurriedly and transport them to the theater of operation in the minimal time possible. Hurried examinations did not permit the close observations that are being made today. It is essential for the men being inducted into the Army at the present time to be capable of efficient work and hard living, and to

1 Second Report of the Provost Marshal General to the Secretary of War on the Operations of the Selective Service System to Dec. 31, 1918. Washington: D. C. Government Printing Office, 1919

be otherwise capable of handling the more complicated procedure and mechanics of the modernized army.

The average height of recruits examined during the World War was 67½ inches (171 cm.), the average weight was 142 pounds (64 Kg.) and the average chest

TABLE 4.—Occupations of 19,923 Registrants
Physically Examined

Occupation	Number of Registrants Physically Examined	Percentage of Total Examined
Professional workers	390	3.0
Semiprofessional workers	226	1.1
Farmers (owners, tenants and croppers) and farm managers	1,090	5.5
Proprietors, managers and officials, except farm	779	3.9
Clerical and kindred workers.....	1,548	7.8
Salesmen	878	4.4
Craftsmen, foremen and kindred workers.....	1,670	8.4

Domestic service workers.....	56	0.3
Protective service workers.....	64	0.3
Service workers, except domestic and protective	936	4.7
Farm laborers and foremen.....	1,683	8.4
Laborers, except farm and mine.....	2,487	12.5
Nonclassifiable returns	571	2.9
Emergency workers and unemployed.....	3,042	15.3
Students	221	1.1
Total.....	19,923	100.0

measurement in forced expiration was 33½ inches (84 cm.). It is estimated that the average height in men examined for military service in the federal forces during the Civil War was 67½ inches (171 cm.), the average weight was 136 pounds (61.7 Kg.) and the

average chest measurement at expiration was 33½ inches (84 cm.).² In Canada the average height of registrants being examined for military duty is 66⅔ inches (169 cm.), the average weight 144⅔ pounds (65.5 Kg.) and the average age 22½ years. Comparison of defects with those found in men entering the Canadian army is not possible, owing to the fact that the examination given is primarily a coarse screening as compared to the thorough examination in this country. The principal causes of rejection in Canada are defects of the feet and nose, and hernias.

The administration by the Selective Service System and the Army of what might be considered fairly high physical standards has produced, unqualifiedly, an army with the best physical condition of any comparable sized army in history. In many cases such modern conveniences as automobiles, street cars, elevators and household gadgets have produced flabbiness of muscle and at times paunchiness in the waistline. This, however, is not to be confused with soundness of health, which is determined more by sturdiness of framework, a sound heart, sound lungs and respiratory system, a good digestive system and a stable mental and nervous system. The vast majority of registrants can be hardened by training. This does not mean, however, that we should overlook the warning signaled to us by the discovery of this huge number of hidden defects and diseases in such a large proportion of the registrants.

SPECIALISTS SHARE FEES WITH MEMBERS IN MILITARY SERVICE

Recognizing the financial sacrifice which members of its organization who have gone into the military service have made, the Indianapolis Ophthalmological and Oto-Laryngological Society has adopted a resolution to the effect that 50 per cent of all fees collected by members from patients who belong to the practice of any member engaged in military service shall be remitted to such members until they return to civil practice; also that on return from military service to civil practice of such members, all patients belonging to their prior practice shall be returned to them by those members who may come into professional contact with such patients. The society also voted to waive all dues and assessments of those who enter the military service and shall consider such members in good standing in that society for the duration of their military service and for the period of one year thereafter.

FUNCTION OF MEDICAL ADVISORY BOARDS (VI)

Memorandum (1-403) Concerning Relationships of Medical Examinations by Induction and Advisory Boards

It has been brought to the attention of this headquarters that in some of the corps areas registrants are being referred back to local boards and medical advisory boards by the examining and induction stations for additional examinations, including laboratory and x-ray tests, to determine their physical qualifications for induction.

The Medical Advisory Board is an element of the Selective Service System. There is no objection to the use by the Army of the specialists on such boards provided the cost is borne by the Army and it is distinctly understood that such services are rendered to and for the Army. In no event should a registrant be referred back to local boards for an additional examination prior to a final action by the examining and induction stations.

A problem arises, not infrequently, at the examining and induction stations, where the registrant declares that he suffers from epilepsy, asthma or other conditions and yet presents no proof other than his bare statement. Because of lack of acquaint-

tance with the registrant, the examiner naturally is uncertain as to the truth or falsity of the statement. If such cases are rejected and returned to the local board, a statement will be made by the examining and induction stations under remarks on the "Report of Physical Examination and Induction" (form 221), giving the basis for the cause of rejection. If the local board or its examining physician has reason to believe that the registrant has falsified such a statement, it may accumulate evidence to justify its belief and return the registrant at a subsequent date, accompanied by such evidence.

LEWIS B. HERSHEY,
Director, Selective Service System.

PRICE OF RUBBER DRUG SUNDRIES

Manufacturers of rubber drug sundries, including essential hospital and medical items, were requested not to advance prices above those in effect on March 1 in a letter sent to them by Acting Price Administrator John E. Hamm of the Office of Price Administration. The purpose of the request is to keep prices from mounting pending completion of an investigation to determine proper maximum prices for rubber drug sundries. Manufacturers of such items have been allotted a supply of crude rubber and latex by the War Production Board because of the essential nature of the products. It is "essential that prices at all manufacturing and distributing levels reflect only increases which are absolutely necessary for the maintenance of production." Manufacturers will be asked in the near future to submit pertinent cost and earnings data. Manufacturers who intend any change in specifications or quality standards are asked to communicate with the OPA before establishing prices on the altered articles.

NEW ARMY DENTAL CHIEF

Col. Robert H. Mills, D. C., U. S. Army, has been nominated by the President to be Assistant Surgeon General, to succeed Brig. Gen. Leigh C. Fairbank, D. C., who retired on February 28. Colonel Mills has been chief dental surgeon in the Ninth Corps Area.

ORGANIZATION SECTION

OFFICIAL NOTES

INDUSTRIAL HEALTH

Report of a Joint Session Between the Subcommittee on Industrial Health and Medicine, Federal Security Agency, and the Council on Industrial Health, American Medical Association

The Subcommittee on Industrial Health and Medicine of the Federal Security Agency and the Council on Industrial Health met jointly in Chicago on Sunday, January 11. Those present were Stanley J. Seeger, Harvey Bartle, Leverett D. Bristol, Warren F. Draper, Philip Drinker, Leroy U. Gardner, Raymond Hussey, Anthony J. Lanza, Robert T. Legge, Clarence D. Selby, Roscoe L. Sensenich, Olin West, Carl M. Peterson, James A. Crabtree, E. C. Holmblad, Lloyd Nofand, George M. Smith, Capt. T. C. Bedwell, J. J. Bloomfield, Licut. Comdr. Otto L. Burton, J. G. Cunningham, Comdr. Edward H. Cushing, Morris Fishbein, Don Hogate, O. J. Johnson, R. G. Leland, Major Sam F. Seeley, James Sterner and James T. Townsend.

To aid the medical profession in extending and improving its contribution to industrial medical service, medical societies in states and counties have been supplied with a program which will accelerate preparation. Medical and professional schools also have improved and expanded training programs. At present a joint report prepared by the Council on Industrial Health and the American Association of Industrial Physicians and Surgeons on improved industrial health education is in final stages of revision preceding publication and wide distribution to medical educators and organizations.

If industry is to absorb the products of accelerated industrial health education, some concomitant program of training industry in the advantages of medical supervision over workers is indispensable. The principal problem relates to small plants which are, or consider themselves, unable individually to support medical and nursing programs.

The Division of Industrial Hygiene of the U. S. Public Health Service reported that greater effort will be necessary to establish cooperation between bureaus of industrial hygiene and committees on industrial health in the various states. The annual budget for industrial hygiene in the U. S. Public Health Service amounts to about \$650,000. Of the one hundred and sixty-one employees in the division, twenty-four are physicians and twenty-three are engineers. Medical and engineering studies have been conducted in government owned ordnance plants, quartermaster corps depots and air corps plants. Recommendations are being put into effect. Fifty-five government owned privately operated ordnance plants are certified for similar study. A reliable test for night vision is being sought, useful in the selection of pilots, truck drivers and night workers under black-out conditions. Other studies are to help in the selection of airplane pilots and bombardiers. Thirty-six states, four cities, two counties and two territories conduct industrial hygiene bureaus requiring a budget of \$1,000,000 for 1942. During the year ended June 30, 1941, 6,084 investigations were made involving 1,509,797 workers. These bureaus cooperate with the National Committee for the Conservation of Man Power in Industry and attempt to investigate plants having Walsh-Healy contracts. These state bureaus also supply consulting service in relation to dermatoses, nursing and sick absenteeism reporting. Over 90 per cent of the work of the research section of the Division of Industrial Hygiene deals with toxicity of explosives, solvents, chemicals and metals, the development of instruments for detection and measurement of exposures, high altitude effects, fatigue, and crowded working and living conditions. Miscellaneous activities include the preparation of a

bibliography on mental hygiene in industry, inspection of plant medical services, development of educational pamphlets, radio scripts and films, preparation of technical standards in cooperation with the American Standards Association and advancement of plans for industrial nursing services, mainly of a part time character, to small industrial establishments.

Since adequate personnel is basic to a solution of medical service in industry, the Procurement and Assignment Service is charged with the avoidance of raiding industry of essential physicians and will do so if sufficient numbers of eligible medical people are available to fill military requirements. A reserve officer must immediately make a definite determination whether he is essential for industry or not and submit necessary representations to the adjutant general's office to obtain temporary *deferment*. Other physicians under 45 who are physically fit must be certified as absolutely essential to industry by the managements which hire them. Physicians in the 45 to 60 groups will be dislocated if certain specialist classifications are called up. In the over 60 group, dislocation is considered unlikely.

As substitutes for eligible and replaceable industrial physicians, reliance should be directed to physically unfit male physicians under 45, male physicians over 45, women physicians and, where possible, qualified laboratory and technical personnel whose employment in appropriate service would release an otherwise essential physician. Everything depends on the willingness of physicians on self analysis supplemented by advice from referees in counties, districts, states and corps areas to determine the physician's own greatest sphere of usefulness. Instructions will soon be issued enabling each physician to align himself with service most consistent with his individual ability and physical equipment. Every physician will receive a certified serial number of his enrolment and an identifying button that only he will be authorized to wear.

Commissions on inactive status are under consideration in the U. S. Public Health Service, to be assigned to needed public health officers, physicians and sanitary engineers in order to have available means for coping with disaster and epidemics.

In order to acquaint the small manufacturers with the benefits of industrial health, it was agreed that some agency for public information be created. It was suggested that failure in this regard might logically lead to compulsory forms of industrial medical service. Specific suggestions included a presidential proclamation, followed by a broad but intensive campaign through newspaper and magazine articles, and organized promotion through local manufacturers' associations, chambers of commerce, civic organizations, medical publicity bureaus and every other accessible avenue. To implement these suggestions it was variously recommended:

(a) That a small conference be called soon in Washington to canvass the possibilities for better coordination in industrial health programs having particular reference to current plans in the Office for Civilian Defense and for creating an agency for public information.

(b) That the facilities of the Federal Security Agency be used to gain the same end.

(c) That the Subcommittee on Industrial Health and Medicine be enabled to employ necessary publicity talent.

(d) That the practicing physician can and must be relied on to provide medical service for small industry and that all programs of publicity and activities both in industrial hygiene and in civilian defense should bear this fact strongly in mind.

Although no precise action was taken, it seemed to be the general opinion that the chairman of the subcommittee inquire further into possibilities and that, if it seemed in the interests of the worker and industry, an agency for the dissemination of industrial health information be created. It seemed also to be the consensus that, if created, this agency should be directly attached to the subcommittee.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bill Introduced.—S. 2394, introduced by Senator Bilbo, Mississippi, provides that the Commissioners of the District of Columbia shall cause to be set up facilities and shall appoint such personnel as they may deem necessary for the scientific determination of the degree of intoxication of motor vehicle drivers. The bill also provides for the admission in evidence of the results of the tests.

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 6730 has passed the House, a bill to protect the public health by regulating the mail order business in dentures. A companion bill, S. 2371, introduced by Senator Tunnell, Delaware, is pending in the Senate Committee on Interstate Commerce.

Bills Introduced.—S. J. Res. 140, introduced by Senator Glass, Virginia, proposes to grant permission to Hugh S. Cumming, Surgeon General (retired) of the United States Public Health Service, to accept certain decorations bestowed on him by the republics of Colombia, Haiti and Chile. S. 2405, introduced by Senator George, Georgia, proposes to discharge more effectively the obligations of the United States under certain treaties relating to the manufacture and distribution of narcotic drugs, by providing, through a licensure system, for domestic control of the

production and distribution of the opium poppy and its products. S. 2412, introduced by Senator Pepper, Florida, proposes to provide benefits, including medical care, for the injury, disability, death or enemy detention of civilians and for the prevention and relief of civilian distress arising out of the present war.

STATE MEDICAL LEGISLATION

Virginia

Bill Introduced.—S. 141 proposes, among other things, to authorize the state hospital board to establish and maintain outpatient mental hygiene clinics, to establish and maintain mental health programs and services, and to initiate and direct the development of long range programs and plans with respect to mental hygiene and hospital services provided by the state.

Bill Passed.—S. 178, to amend the insurance law, proposes to authorize corporations issuing motor vehicle liability insurance to add endorsements thereto for the issuance of medical, surgical, ambulance or hospital payments to the insured.

Bill Enacted.—H. 171 authorizes the boards of supervisors of certain counties in the state to establish a retirement system for the employees of such counties and to employ such actuarial, medical and legal aid and assistance in establishing and administering such system as it may deem necessary.

WOMAN'S AUXILIARY

WINNERS IN THE HYGEIA CONTEST

The American Medical Association offered \$400 in cash prizes to the state and county auxiliaries which obtained the largest number of subscription credits to *Hygeia*. The contest covered the period from Sept. 1, 1941 to Jan. 31, 1942.

Cash prizes were awarded as follows:

Group 1. Auxiliaries with a membership of from one to thirteen:

First prize, \$40, to Perry County, Mo., Mrs. B. T. Koon, president, Perryville, Mo.

Second prize, \$25, to Cass County, Mo., Mrs. David S. Long, Hygeia chairman, Harrisonville, Mo.

Third prize, \$15, to Childress-Collingsworth-Hall counties, Texas, Mrs. J. A. Odum, Hygeia chairman, Memphis, Texas.

Group 2. Auxiliaries with a membership of from fourteen to twenty-three:

First prize, \$40, to Chelan County, Wash., Mrs. R. S. Mitchell, Hygeia chairman, Wenatchee, Wash.

Second prize, \$25, to Cowlitz County, Wash., Mrs. C. J. Sells, Hygeia chairman, Longview, Wash.

Third prize, \$15, to Twin Falls County, Idaho, Mrs. C. B. Beynier, Hygeia chairman, Twin Falls, Idaho.

Group 3. Auxiliaries with a membership of from twenty-four to forty-two:

First prize, \$40, to Walla Walla Valley, Wash., Mrs. J. T. Rocks, Hygeia chairman, Walla Walla, Wash.

Second prize, \$25, to Bowie-Miller counties, Texas-Ark., Mrs. Ralph Cross, Hygeia chairman, Texarkana, Texas.

Third prize, \$15, to Vermillion County, Ill., Mrs. C. L. Bennett, Hygeia chairman, Danville, Ill.

Group 4. Auxiliaries with a membership of from forty-three to six hundred:

First prize, \$40, to Westmoreland County, Pa., Mrs. I. J. Ober, Hygeia chairman, Greensburg, Pa.

Second prize, \$25, to Buchanan County, Mo., Mrs. Charles H. Werner, Hygeia chairman, St. Joseph, Mo.

Third prize, \$15, to Cook County, Ill., Mrs. Clyde R. Landis, Hygeia chairman, Chicago.

State winners:

First prize, \$40, to state of Washington, Mrs. Delmar F. Bice, Hygeia chairman, Yakima, Wash.

Second prize, \$25, to state of Illinois, Mrs. E. M. Egan, Hygeia chairman, Chicago.

For the third prize, \$15, no state qualified by sending in their quota of subscriptions.

Honorable Mention was given to the following counties:

Santa Barbara County, Calif., Mrs. H. E. Henderson, chairman, Santa Barbara.

Arapahoe County, Colo., Mrs. H. B. Catron, chairman, Englewood.

Richmond County, Ga., Mrs. E. S. Sanderson, chairman, Augusta.

Bannock-Bingham County, Idaho, Mrs. W. W. Beek, chairman, Blackfoot.

Rock Island County, Ill., Mrs. Samuel Brown, chairman, East Moline.

Wayne County, Mich., Mrs. F. T. McCormick, chairman, Detroit.

Muskogee County, Okla., Mrs. J. T. Woodburn, Muskogee.

Mercer County, Pa., Mrs. Paul T. Hope, chairman, Mercer.

Spartanburg County, S. C., Mrs. W. T. Hendrix, chairman, Spartanburg.

Snohomish County, Wash., Mrs. Lewis J. Ferrell, chairman, Everett.

Raleigh County, W. Va., Mrs. A. C. Echols, chairman, Prince.

Brown-Kewaunee-Door counties, Wis., Mrs. L. D. Quigley, chairman, Green Bay.

Other counties that have reached or exceeded their quota were Kern County, Calif.; Monterey-San Benito County, Calif.; Riverside County, Calif.; Duval County, Fla.; Sangamon County, Ill.; Dubuque County, Iowa; Shawnee County, Kan.; Renville County, Minn.; Greene County, Mo.; Jackson County, Mo.; Montgomery County, N. Y.; Pottawatomie County, Okla.; Marion-Polk County, Ore.; Berks County, Pa.; Bucks County, Pa.; Crawford County, Pa.; Mifflin County, Pa.; Clark County, Wash.; King County, Wash.; Pierce County, Wash.; Whitson County, Wash.; Yakima County, Wash.; Kenosha County, Wis.; Racine County, Wis.; Rock County, Wis.

This year's contest resulted in eight thousand one hundred and seventy-four subscriptions.

To the Hygeia chairmen, officers and members of the various county and state woman's auxiliaries who have assisted in making this contest a success, Mrs. George R. Dillinger, national Hygeia chairman, and the circulation manager of *Hygeia* express appreciation.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

New Health Officer for Birmingham.—Dr. George A. Denison, acting health officer of Birmingham and Jefferson County since September, has been appointed health officer, effective February 25. Dr. Denison graduated at Baylor University College of Medicine, Dallas, Texas. He has been connected with the Jefferson County health unit since 1921. From 1931 until his appointment as acting health officer he served as director of the bureau of laboratories.

State Medical Meeting in Montgomery.—The annual session of the Medical Association of the State of Alabama will be held at the Whitley Hotel, Montgomery, April 21-23, under the presidency of Dr. James M. Mason, Birmingham, and with the Montgomery County Medical Society acting as host. Included among the speakers will be:

Dr. Ralph McBurney, Tuscaloosa, A Clinical Evaluation of the Erythrocyte Sedimentation Rate.

Dr. Henry B. Burdeshaw, Dothan, Blood and Blood Substitutes in the Treatment of Hemorrhage and Shock.

Drs. Frank A. Kay, James D. Smith and Norman H. Reim, Tuscaloosa, Electric Shock Treatment in Psychiatric Disorders.

Dr. French H. Craddock Jr., Sylacauga, Intravenous Alcohol in Post-operative Analgesia.

Dr. Ralph M. Clements, Tuscaloosa, A Newer Treatment for Pseudo-Typhoid.

One general session will be addressed by out of state physicians, Drs. Edward L. Compere, Chicago, speaking on "The Treatment of Compound Fractures" and Frank E. Adair, New York, "Carcinoma of the Breast." Part of another general session will be devoted to a panel discussion on poliomyelitis by Drs. Daniel G. Gill, Montgomery, epidemiology; Albert E. Casey, New Orleans, pathology; Carl A. Grote, Huntsville, the acute state, and H. Earle Convell, Birmingham, muscular rehabilitation. Dr. Harvey B. Stone, Baltimore, will deliver the Jerome Cochran Lecture Wednesday morning on "Biliary Diseases as Seen by the Surgeon."

CONNECTICUT

Section for Industrial Physicians.—With the February issue, *Connecticut Industry*, official organ of the Manufacturers Association of Connecticut, will conduct a regular column to promote an exchange of ideas among industrial physicians to help further the adoption of improved industrial medical procedures in Connecticut industries.

Grant for Research on Child Development.—The Carnegie Corporation of New York has given a grant of \$10,000 to support a research program at the Clinic of Child Development at Yale University School of Medicine, New Haven. The clinic, which was founded in 1911 by Dr. Arnold L. Gesell, its present director, is investigating the mental growth of normal infants and devising clinical methods for the early diagnosis of developmental defects and deviations. Staffed by pediatricians and psychologists, it maintains a diagnostic and advisory service for infants and preschool children, a guidance nursery, a photographic research library and special facilities for one way vision observation and for systemic studies of normal and abnormal child behavior.

DISTRICT OF COLUMBIA

Biochemist Receives Hillebrand Award.—Michael X. Sullivan, Ph.D., since 1931 director of the Chemo-Medical Research Institute, Georgetown University School of Medicine, Washington, was presented with the Hillebrand Award of the Chemical Society of Washington at the annual dinner, March 12, for his work on the "Sulfur-Containing Substances of the Body." Dr. Sullivan received his Ph.D. at Brown University, Providence, R. I., in 1903. He served as fertility expert at the Bureau of Soils, U. S. Department of Agriculture, from 1907 to 1915 and as biochemist to the U. S. Public Health Service from 1915 to 1931. He was president of the Washington Section of the American Chemical Society in 1914.

Hospital Meeting.—The fifth annual meeting of the Medical Society of St. Elizabeths Hospital, Washington, will be addressed, April 18, by Dr. Lucille Dooley, Washington, on "Psychoanalytical Concepts of Manic Depressive Psychosis";

Nathan Bryllion Fagin, Ph.D., Baltimore, "The Influence of Psychoanalysis on Modern Literature"; Dr. Uno H. Helgeson, Commander, U. S. Naval Reserve, Washington, "Acute Traumatic Neuroses Following Combat," and Dr. Winfred Overholser, Washington. Elmer Louis Kayser, Ph.D., Washington, will be the speaker at the annual dinner.

FLORIDA

State Medical Meeting in Hollywood April 13-15.—The sixty-ninth annual meeting of the Florida Medical Association will be held at the Hollywood Beach Hotel, Hollywood, April 13-15, under the presidency of Dr. Walter C. Jones Jr., Miami. The Palm Beach County Medical Society will be host at the session. Included among the speakers will be:

Dr. Lauren M. Sompayrac, Lieutenant, U. S. Navy, Naval Hospital, Jacksonville, The Dermatologist in the Navy.

Dr. James A. Bradley, St. Petersburg, Bed Rest in Coronary Thrombosis.

Dr. Nathan S. Rubin, Major, U. S. Army, Station Hospital, Panama City, Some Medical Problems of Flight.

Dr. Daniel C. Elkin, Atlanta, Ga., Injuries of the Chest.

Dr. Harold G. Nix, Tampa, Use of Vitamin K in Obstetrics.

Drs. Wilfred McL. Shaw and William Tracy Haverfield, Jacksonville, Roentgen Aids in the Diagnosis and Localization of Intracranial Conditions.

Dr. Warren W. Quillian, Coral Gables, Pyurias in Childhood: Their Significance and Treatment.

Other groups meeting at this time include the Florida section of the American College of Physicians, the Florida Radiological Society, the Florida Pediatric Society and the Florida Association of Dermatology and Syphilology. Dr. Cornelius F. Holton, Savannah, Ga., will discuss "Industrial Surgery" before the Florida Association of Industrial Surgeons, and Dr. Frank E. Burch, St. Paul, "Cataracts" and "Glaucoma" before the Florida Society of Ophthalmology and Otolaryngology. The sixteenth annual meeting of the woman's auxiliary to the state medical association will be held, April 13-15.

ILLINOIS

Change in Hospital Superintendents.—Dr. Joseph H. Ellingsworth, Geneseo, has been appointed managing officer of the Peoria State Hospital, succeeding Dr. Philip Waters, who has assumed a similar position at the East Moline State Hospital. Dr. Waters fills the vacancy that occurred when Dr. Joseph A. Campbell resigned.

Coordinators Named to Protect Water Supply.—A group of coordinators from ten emergency water corps zones has been appointed to work toward the protection and conservation of existing water supply systems in more than six hundred down state municipalities. A meeting was held in Springfield, March 12, under the auspices of the state department of health to map out regulations and programs for local application.

Chicago

Society News.—Dr. Frederic Schreiber, Detroit, discussed "Clinical Relationship Between Cerebral Anoxia and Anesthesia" before the Chicago Society of Anesthetists, February 25.—The Chicago Laryngological and Otological Society was addressed, March 2, by Drs. John H. Gilmore on "X-Ray Studies in Mastoid Pathology"; Oliver McGillivuddy, Lansing, Mich., "Encephalomenigeoceles in the Nasal Cavities," and Mauritius Tamari, "Histopathologic Changes of the Temporal Bone in Paget's Disease."—The Illinois Psychiatric Society, March 5, was addressed by Drs. Milton Rosenbaum, Cincinnati, "Adaptation of the Central Nervous System to Alcohol"; James Clark Moloney, Detroit, "Unconscious Motivations for the Choice of Employment," and Maxwell Gitelson, "The Critical Moment in Psychotherapy."—The North Shore Branch of the Chicago Medical Society will be addressed at the Sovereign Hotel, April 7, by Dr. Bayard T. Horton, Rochester, Minn., on "Headaches: Clinical Types and Treatment." The North Side Branch was addressed, March 5, by Drs. Ernest H. Falconer, San Francisco, on "Hodgkin's Disease, with Special Reference to Skeletal and Bone Marrow Involvement" and Edward L. Bortz, Philadelphia, "Geriatrics: A New Light on Old Folks."

LOUISIANA

State Medical Meeting.—The Louisiana State Medical Society will hold its annual meeting in New Orleans, April 27-29, under the presidency of Dr. Paul King Rand, Alexandria. Among the out of state speakers will be Dr. Jacob Arnold Bargen, Rochester, Minn., on "The Use of Sulfonamide Derivatives in the Digestive Tract"; Charles T. Stone, Galveston, Texas, "The Future of the Coronary Thrombosis Patient"; Adolph B. Loveman, Louisville, "Some Cutaneous Manifestations of Systemic Disorders," and Roy F. Baskett, Texarkana,

Ark., "The Use of the Various Insulins in the Treatment of Diabetes Mellitus." The program will include the following local physicians:

Dr. Frank L. Loria, New Orleans, Abdominothoracic Gunshot Injuries.
Drs. Bjarne Pearson and Manuel M. Garcia, New Orleans, Spread and Metastasis in Carcinoma of the Cervix Uteri.
Drs. Daniel N. Silverman, Robert A. Katz and Andrew V. Friedrichs, New Orleans, The Increasing Incidence and Complications of Chronic Bacillary Dysentery.
Dr. Charles R. Gowen, Shreveport, The Rational Management of Bronchiectasis.
Drs. Louis S. Charbonnet Jr. and George F. Schroeder, New Orleans, The Physiologic Conception of Tissue Resistance in the Surgical Diabetic.

One session will be devoted to a symposium on "Health Protection of Civilians in the Present War" to cover the subjects of nutrition, emergency water supply and sewage disposal, potential epidemics in Louisiana, protection by immunization and provisions for children.

MICHIGAN

New Director of Epidemiology.—Dr. Thaddeus M. Koppa, assistant director of epidemiology, Michigan State Department of Health, Lansing, has been appointed director, newspapers report. He succeeds Dr. Wallace M. Chapman, who has resigned to enter private practice in California. Dr. Chapman was named to the position last year.

Health Center Opened.—The new Delta County Health Center at Escanaba was opened formally to the public on February 28. The center is in a former school building, which was remodeled to meet the needs for offices of the county school commissioner and for the health unit of the county. There are six rooms, a library and a meeting room with a seating capacity of between seventy-five to one hundred persons. Dr. Fred O. Tonney, Escanaba, is director of the county health unit.

MINNESOTA

Meeting of Radiologists.—The spring meeting of the Minnesota Radiological Society was held at the Mayo Foundation House, Rochester, March 28. The speakers included the following Rochester physicians:

Drs. William C. MacCarty Jr. and Byrl R. Kirklin, Radiologic and Pathologic Studies of Prepyloric Ulcer.
Drs. Frank J. Rigos, Oak Terrace, and John D. Camp, Primary Tumors of the Ribs.
Drs. James T. Sheldon and Walter C. Popp, X-Ray Treatment of Erysipelas.
Drs. Robert D. Moreton and Eugene T. Leddy, Dysgerminomas with Reference to Radiosensitivity.
Drs. George R. Dochat and Malcolm B. Dockerty, Prognosis in Carcinoma of the Stomach in Relationship to Duke's Type and Broder's Grade of Malignancy.

At the evening session Dr. Patrick P. T. Wu, Tsang, Peiping, China, gave an address entitled "China Speaks."

MISSOURI

State Meeting in Kansas City April 27-29.—The annual session of the Missouri State Medical Association will be held in the Municipal Auditorium, Kansas City, April 27-29, under the presidency of Dr. Robert B. Denny, Creve Coeur. Out of state speakers will include:

Dr. Karl W. Brimmer, Washington, D. C., Faith, Hope and Cure—Alls.
Dr. William Walters, Rochester, Minn., Gastric Ulcer.
Dr. Willard R. Cooke, Galveston, Texas, Three Important Advances in Obstetric Therapy: Analgesia, Intravenous Ergotrate in Third Stage of Labor, Magnesium Sulfate in Eclampsia.
Dr. George R. Herrmann, Galveston, Some Medical Emergencies and Their Management.
Dr. Russell L. Haden, Cleveland, The Differentiation of Obstructive Anemia.
Dr. Cobb Pilcher, Nashville, Tenn., Neurosurgery in the War.
Dr. Joe Vincent Meigs, Boston, Endometriosis.
Dr. Arthur Purdy Stout, New York, Clinical Diagnosis of Cancer of the Breast.
Dr. Robert Elman, St. Louis, The Correction of Acute Protein Deficiency in the Treatment of Surgical Shock, Severe Hemorrhage and Burns.
Dr. Hobart A. Reinmann, Philadelphia, Practical Aspects of Newly Discovered Forms of Pneumonia.
Dr. Harris B. Shumac, Value of Sympathectomy in the Treatment of ders.
Dr. Irvine H. Page, and Its Experimental Treatment.
Dr. Raymond O. Muelther, St. Louis, Blood Banks.
Dr. Oliver Cope, Boston, Hyperthyroidism.
Dr. William B. Kountz, St. Louis, The Recognition and Treatment of Degenerative Health Disease.
Donald E. Cummings, B.S., Denver, Industrial Health.

The annual banquet, Monday evening, will be addressed by Dr. George F. Lull, colonel, M. C., U. S. Army, Washington, D. C., on "The Medical Officer in Our Wartime Army." Dr. Willard R. Cooke will also address the maternal welfare luncheon meeting.

NEW HAMPSHIRE

Changes in Board of Health.—Dr. Ralph E. Miller, associate professor of pathology and assistant dean of Dartmouth Medical College, Hanover, has been chosen president of the state board of health to succeed Dr. George C. Wilkins, Manchester, who retired after serving in this capacity for many years. The latter had been a member since 1915. Dr. Montfort Haslam, Antrim, has been named a member of the board, succeeding Dr. James W. Jamson, Concord, a member since 1933, who also retired.

NEW JERSEY

Health Officers Association.—Mr. W. Stanley Applegate, Asbury Park, was elected president of the New Jersey Health Officers' Association, succeeding Mr. Harold W. Hager, Ocean City; Mr. Hugh B. Martin, Englewood, was elected vice president and Mr. William C. Black, Princeton, reelected secretary-treasurer.

NEW YORK

Public Sunday Medical Lectures.—As a public service and a contribution to the war effort, the University of Buffalo School of Medicine, Buffalo, recently conducted a series of five public lectures on "The Care of Your Health During the War." The lectures, which were given in the amphitheater of the medical school, started on February 8. The medical school gave a course of public lectures last year also as a community service.

Fifty Years as Health Officer.—Dr. Morris W. Cowden, Gerry, Chautauqua County, was recently presented with a testimonial letter by Dr. Edward S. Godfrey Jr., state health commissioner, "in recognition of fifty years of faithful and continuous service as health officer." Dr. Cowden graduated at the University of Buffalo School of Medicine in 1890. He had been practicing in Gerry for two years when he was named health officer. Dr. Cowden has retired from active practice but still carries on as local health officer.

Maternal and Child Welfare Teaching Day.—A group of local agencies sponsored a regional maternal and child welfare teaching day at the Rochester General Hospital, Rochester, April 1. Included among the speakers were:

Drs. Donald H. Kariher and Howard A. Spindler, Rochester, The Role of the Blood Rh Factor in Transfusion Reactions and Erythroblastosis Fetalis.
Dr. John M. MacMillan, Rochester, Tuberculosis and Pregnancy.
Dr. Herbert C. Soule, Rochester, The Care of the Premature Infant.
Dr. Charles S. Lakeman, Rochester, The Diagnosis and Treatment of Thrombophlebitis.
Dr. Clarence Arthur Elden, Rochester, The Treatment of Habitual Abortion.
Dr. Ferdinand J. Schoeneck, Syracuse, Demonstration of Case Study.

Dr. Harvey B. Matthews, Brooklyn, clinical professor of obstetrics and gynecology, Long Island College of Medicine, addressed the evening session at the Rochester Academy of Medicine on "Prolonged Labor: Etiology and Management."

New York City

The Janeway Lectures.—The annual Edward Gamaliel Janeway Lectures at Mount Sinai Hospital will be delivered by Michael Heidelberger, Ph.D., associate professor of biochemistry, Columbia University College of Physicians and Surgeons, April 7 and April 10. His subject will be "Newer Concepts of Infection and Immunity and Chemistry's Part in Their Development."

Physician Wins Town Hall Essay Contest.—Dr. Jacob Sobel, attending pediatrician at the Hospital for Joint Diseases and Beth David Hospital and director of pediatrics at Gouverneur Hospital, recently won first prize of \$250 in the national essay contest sponsored by Town Hall in connection with its radio forum, America's Town Meeting of the Air. The subject was "What Must We Do to Improve the Health and Well-Being of the American People?" Dr. Sobel graduated at Columbia University College of Physicians and Surgeons in 1895.

Dr. Bernecker New Commissioner of Hospitals.—Dr. Edward M. Bernecker, general medical superintendent for the city department of hospitals, has been named commissioner of hospitals to succeed Dr. Willard C. Rappleye, resigned. Born in Seward, Neb., March 13, 1892, Dr. Bernecker graduated at the Halmemann Medical College and Hospital in Chicago in 1915. He served his internship at Metropolitan Hospital. In 1917 he entered the U. S. Army and was appointed a surgeon in the air service. According to the New York Times he was stationed in the second A. E. F. training section at Tours in France and later was appointed a battalion surgeon in the second division. After the war he returned to Metropolitan

Hospital as deputy superintendent, becoming superintendent in 1930. In 1935 he became deputy superintendent of the Kings County Hospital, leaving the position in 1937 to become general medical superintendent for the department of hospitals.

Professional Service Building Dedicated.—The Hospital for Joint Diseases February 7 dedicated its new professional service building, the Melanie Faith Polachek Courmand Memorial. The building is seven stories high and contains professional facilities and services to serve both outpatients and inpatients. The first floor contains emergency room, admitting offices for ward patients, medical emergency field unit and the central offices of the social service department. The physical therapy department is on the second floor and the radiology service on the third. The Women's Division, including facilities for about two hundred and fifty women volunteers, sewing rooms for hospital linens, patients' circulating library and reading room and the occupational therapy department, is on the fourth floor. The fifth floor contains a blood bank, bacteriology laboratory and an auditorium; the sixth, laboratories for surgical pathology, clinical pathology and research; the seventh, animal operating rooms. The various units were financed by individual donors.

Physicians Honored by Polyclinic Hospital.—Exercises were held at the Polyclinic Medical School and Hospital, February 10, to honor twenty-three physicians and surgeons "deemed to have contributed most toward the creation" of the hospital. Portraits of the physicians were unveiled. Dr. Orrin S. Wightman, formerly president of the state medical society, presented the portraits to the hospital and Dr. Joseph F. McCarthy, president of the faculty, accepted the gift, which is said to represent graphic portrayal of the sixty-one year history of Polyclinic Hospital. The complete list of those whose portraits appear in the gallery follows: Drs. Willard Parker, Paul F. Munde, Andrew R. Robinson, Landon Carter Gray, Abraham Jacobi, Walter Gill Wylie, Arpad G. Gerster, Virgil P. Gibney, D. Bryson Delavan, Luther Emmett Holt, Bernard Sachs, James P. Tuttle, James Riddle Goffe, William Rice Pryor, Robert C. Myles, Frederick Whiting, Charles Gilmore Kerley, John A. Bodine, Royal Whitman, Orrin S. Wightman, Frederick H. Dillingham, John Allen Wyeth and Harry Marion Sims. With the exception of seven men, Drs. Delavan, Sachs, Whiting, Kerley, Whitman, Wightman and Dillingham, the honored men are dead.

OHIO

Regional Meeting on Anesthesia.—The American Society of Anesthetists, Inc., the Ohio State Section of the national society and the Ohio Society of Anesthetists will meet at the Neil House, Columbus, April 30, for the following program:

- Dr. Norris E. Lenahan, Columbus, Intravenous Anesthesia.
- Dr. Harold D. Green, Cleveland, Shock.
- Dr. James H. Bennett, Cincinnati, The Anesthetic Management for Drainage of Abscess of the Submandibular Space.
- Dr. Kenneth C. McCarthy, Toledo, Casualty Anesthesia in England.
- Drs. John K. Potter and Reynold M. Crane, East Cleveland, Anesthesia in Thyroid Surgery.
- Dr. Abe L. Schwartz, Cincinnati, The Use of PicROTOXIN in Barbiturate Poisoning.

New Professor of Dermatology and Syphilology.—Dr. Harry L. Claassen, assistant professor of dermatology and syphilology at the University of Cincinnati College of Medicine, has been promoted to professor, effective March 3. He fills the vacancy caused by the death of Dr. Elmore B. Tauber, Jan. 23, 1941. Dr. Claassen has been assistant professor and acting head of the department. With his promotion Dr. Claassen also became director of the service of dermatology and syphilology in the Cincinnati General Hospital. He graduated at Cincinnati in 1918 and has been a member of the staff since 1922.

Annual Postgraduate Day.—The Mahoning County Medical Society will observe its annual postgraduate day at the Pick-Ohio Hotel, Youngstown, April 15, with the following program:

- Dr. Jacob R. Buchbinder, Acute Diffuse Peritonitis: Pitfalls in Diagnosis and Some More Recent Concepts of Treatment; Present Status of Surgery for Duodenal Ulcer.
- Dr. Harry Culver, Traumatic Conditions of the Male Urethra and Bladder; Nonspecific Upper Urinary Tract Infections.
- Dr. Paul S. Rhoads, Clinical Feature and Treatment of Pneumonia, 1941-1942 Season; Hemolytic Streptococcus Infections of the Throat and Nose: Their Importance as a Clinical and Public Health Problem.
- Dr. George H. Gardner, Pelvic Endometriosis—An Increasingly Frequent Clinical Problem; Management of the Barren Marriage.

All the speakers are members of the faculty of Northwestern University Medical School, Chicago.

OREGON

Annual Meeting of Surgeons.—The annual session of the Spokane Surgical Society will be held at the Davenport Hotel, Spokane, April 25, with Dr. Richard B. Cattell, Boston, as the guest speaker. The titles of Dr. Cattell's lectures will be "Diseases of the Thyroid Gland," "Common Duct Obstructions" and "Selection of Operation for Carcinoma of Colon and Rectum."

WISCONSIN

New Tuberculosis Officers.—Dr. George C. Owen, Oshkosh, was recently elected president of the Wisconsin Trudeau Society; Dr. Einar R. Daniels, Milwaukee, vice president, and Dr. John D. Steele Jr., Milwaukee, secretary.

Dearholt Fund to be Continued.—The Dearholt Memorial Fund, established by the late Dr. Hoyt E. Dearholt, Milwaukee, former executive secretary of the Wisconsin Anti-Tuberculosis Association, will be maintained permanently, it has been announced. Tuberculosis institutes at Marquette University School of Medicine, Milwaukee, and the University of Wisconsin Medical School, Madison, as well as at sanatoriums throughout the state, are made possible by the fund. Dr. Dearholt started the fund by making deductions from his salary as secretary of the association.

Physician Honored.—More than a hundred former patients of Dr. George V. I. Brown gave a dinner in his honor in Milwaukee, February 15. Dr. Brown, who is 80 years of age, recently retired from active practice and is doing consultation work only. He was professor of oral and plastic surgery at the University of Wisconsin Medical School, Madison, from 1920 until he retired as emeritus professor in 1937. During World War I he was called to the Office of the Surgeon General, Washington, as chief of the plastic and oral service at Walter Reed Hospital. Under the orders of General Gorgas he established a school for training men in plastic surgery at Fort Oglethorpe, Ga., before they went overseas.

GENERAL

Blood Plasma Package Wins Award.—Sharp and Dohme, Inc., was given the top award in the drugs, chemicals and drug sundries classification of the eleventh annual All-America Package Competition sponsored by *Modern Packaging Magazine* recently for a package developed to supply dehydrated human blood in a portable, practical and stable form for use in war and civilian practice. The package is supplied as a complete unit with the exception of the intravenous outfit, which is supplied in a separate package and is always included with each order unless otherwise specified.

Grants for Research.—William R. Warner & Company, Inc., New York, has announced grants for medical research as follows:

The Long Island College of Medicine, Brooklyn, a two year fellowship for postgraduate study in the department of radiology.

New York University College of Medicine, New York, for the study of the conjugation of the sulfonamide drugs. This study will be carried out in the pneumonia service of the Harlem Hospital.

Northwestern University Medical School, Chicago, for the study of toxic factors as observed in the department of dermatology investigating the possibilities of detoxifying therapeutic agents used in the practice of dermatology.

Washingtonian Hospital, Boston, for the study of alcoholism involving the blood chemistry and psychometric findings of cases while under the influence of alcohol and during recovery.

Changes in Status of Licensure.—The California State Board of Medical Examiners reports the following:

Dr. Howard D. Mayers, Fall River Mills, license revoked, Oct. 22, 1941, for habitual intemperance.

Dr. Frederick William Riley, Los Gatos, license revoked Oct. 23, 1941, charged with aiding and abetting an unlicensed individual, i. e. William F. Hoque, who operated the Valley Rest Home, Los Gatos, where patients were treated with an escharotic paste as an asserted "cure" of cancer.

Dr. Oscar Charles Long, Brawley, license restored October 21; he was placed on five years' probation without narcotic privileges and ordered to report at each Los Angeles meeting.

The Medical Grievance Committee of the New York State Education Department announces the following action:

Dr. Archie Max Fisher, Spencer, N. Y., license revoked in September 1941 for drug addiction.

Director of Planned Parenthood Federation Appointed.—Dr. Claude C. Pierce, until March 1 medical director of the U. S. Public Health Service in charge of district number 1, New York, has been appointed national medical director of the Planned Parenthood Federation of America, Inc., formerly known as the Birth Control Federation of America, Inc., according to an announcement from the society's headquarters in New York. Dr. Pierce graduated at Chattanooga Medical College in 1898. In 1900 he joined the public health service.

In 1918 an act passed by congress creating the United States Interdepartmental Social Hygiene Board became a law. This included the establishment of a division of venereal diseases in the U. S. Public Health Service. Dr. Pierce organized and directed this division as assistant surgeon general in charge for four years, serving also during that time as a member of the Interdepartmental Social Hygiene Board. When the newly created position of district director was established in 1922 he was assigned to Chicago in charge of district number 3. Later he went to Mexico and Cuba to confer with government authorities on sanitary conditions and quarantine restrictions. In 1926 he was assigned to Washington as assistant surgeon general in charge of personnel and accounts. Subsequently he went to Europe for supervision of medical inspection of aliens. In 1937 he was relieved of duty in Europe and assigned as director of public health district number 1 with headquarters in New York City.

Educational Program on Diabetes.—The Metropolitan Life Insurance Company has been conducting an educational program on diabetes during the past year. More than one and one-half million pamphlets were distributed to the public and to interested physicians. New publications for the public were printed. Exhibits, conferences and correspondence were used to interest health officers and health departments in diabetes control. About one hundred and ten meetings have been addressed by the company's examiners or other physicians. A number of state medical societies actively participated in the program. The objectives of this program are a wider recognition of incipient symptoms, the early detection of disease by medical examination and urinalysis, a closer working relationship between the potential or actual diabetic patient and the private medical practitioner, and more thorough and adequate treatment with postponement of mortality, together with more widespread information about the possible preventive factors.

American Pediatric Society.—The fifty-fourth annual meeting of the American Pediatric Society will be held at Skytop, Pa., April 30-May 2. There will be a symposium on children in the civilian defense program and one on the control of communicable diseases in defense areas and among civilian populations. Among the speakers will be:

- Drs. Clement A. Smith and Eugene Kaplan, Boston, Adjustment of Blood Oxygen Levels in Neonatal Life.
Dr. Henry F. Helmholz, Rochester, Minn., Experimental Studies in Treatment of Urinary Infections.
Dr. Lewis K. Sweet, Washington, D. C., Chemotherapy in Acute Gonococcal Conjunctivitis.
Drs. Luther Emmett Holt Jr. and Victor A. Najjar, Baltimore, A Simple Method for the Laboratory Diagnosis of Deficiencies of Thiamine, Riboflavin and Nicotinic Acid.
Dr. Harold L. Higgins, Boston, Some Physiologic Aspects of Acidosis.
Dr. Arthur F. Abt, Dr. L. Marlin Hardy, Chester J. Farmer, A.M., and Jessie D. Maske, all of Chicago, Relation of Vitamin C to Scarlet Fever, Rheumatic Infections and Diphtheria in Children.
Drs. Harold K. Faber and Edward B. Towne, San Francisco, Surgical Treatment of Cranial Synostosis with Special Reference to Prevention of Blindness.
Dr. Bert I. Beverly, Chicago, Anxieties in Childhood.

Annual Meeting of College of Physicians.—The twenty-sixth annual session of the American College of Physicians will be held at the Municipal Auditorium in St. Paul, April 20-24, under the presidency of Dr. Roger I. Lee, Boston. "Medical Horizons" is the theme of the meeting. The program of the general sessions complements that of the clinics, panel discussions and morning lectures, which will be held throughout the week. Included among the speakers of the six general sessions will be:

- Drs. Edgar V. Allen and Nelson W. Barker, Rochester, Minn., Clinical Studies on the Prevention of Venous Thrombosis and Pulmonary Embolism by the Use of a Preparation from Spoiled Sweet Clover Which Prolongs Coagulation and Prothrombin Time of the Blood.
Dr. Oswald F. Hedley, Bethesda, Md., U. S. Public Health Service, The Fraudulent Use of Digitalis to Simulate Heart Disease.
Dr. Walter S. McClellan, Saratoga Springs, N. Y., New Trends in Treatment of Chronic Disease; An Experience in Spa Therapy.
Dr. Martin Henry Dawson, New York, Penicillin as a Chemotherapeutic Agent.
Dr. Chester S. Keefer, Boston, Gramicidin in the Treatment of Local Infections.
Dr. Nathan S. Davis III, Chicago, Factors Which May Influence Senescence.

A symposium on aviation medicine will constitute the afternoon's program at the first general session Monday with the following speakers: Drs. Louis H. Bauer, Hempstead, N. Y., on "A Brief History of Aviation Medicine and the Physical Qualifications for Flying"; John R. Poppen, captain, M. C. U. S. Navy, Washington, D. C., "Effects of High Speed Including Dive Bombing; Acro Embolism," and Harry G. Armstrong, M. C. U. S. Army, Randolph Field, Texas, "Want and the Use of Supplementary Oxygen." On Wednesday afternoon another general session will be devoted to communicable

diseases. At the annual convocation on Wednesday evening, Dr. Lee will deliver his presidential address and Dr. William deB. MacNider, Kenan research professor of pharmacology, University of North Carolina School of Medicine, Chapel Hill, N. C., will give the convocation address on "A Consideration of the Factor of Change in the Animal Organism." The John Phillips Memorial Medal for 1941-1942 will be presented at this meeting.

The Nutrition Foundation.—Sixteen food companies recently cooperated in creating the Nutrition Foundation, Inc., to develop and apply the science of nutrition for the improvement of the diet and health of the American people. Officers include George A. Sloan, New York City Commissioner of Commerce, president; Charles Glen King, Ph.D., professor of chemistry, University of Pittsburgh, vice president; Ole Saltho, formerly director of the Bureau of Food and Drugs, Department of Health, New York, and more recently consultant of the Food and Drug Administration, Federal Security Agency, Washington, D. C., executive secretary, and Karl T. Compton, Sc.D., Cambridge, Mass., president of the Massachusetts Institute of Technology, chairman of the board. The new group held its inaugural dinner on March 12 in New York. On March 16 the organization of a scientific advisory committee for the foundation was announced. Members are Dr. Frank G. Boudreau, executive director, Milbank Memorial Fund, New York; Conrad A. Elvehjem, Ph.D., University of Wisconsin, Madison; Icie M. Hoobler, Ph.D., Children's Fund of Michigan, Detroit; Paul E. Howe, Ph.D., Surgeon General's Office, U. S. Army, Washington, D. C.; Elmer V. McCollum, Ph.D., Johns Hopkins University School of Hygiene and Public Health, Baltimore; Leonard A. Maynard, Ph.D., Cornell University, Ithaca, N. Y.; John R. Murlin, Ph.D., University of Rochester, Rochester, N. Y.; Roy C. Newton, Ph.D., Swift & Co., Chicago; Lydia J. Roberts, Ph.D., Department of Home Economics, University of Chicago; William C. Rose, Ph.D., University of Illinois, Urbana, Ill.; Dr. William H. Sebrell Jr., U. S. Public Health Service, Washington, D. C.; Henry C. Sherman, Ph.D., Columbia University, New York; Dr. Frederick F. Tisdall, University of Toronto, Toronto, Canada, and Robert R. Williams, Sc.D., chemical director, Bell Telephone Laboratories, New York. There is also a food industries advisory committee. The sixteen founder companies of the new foundation have guaranteed \$10,000 a year each for over a five year period, although it is hoped that eventually increased funds will be received to expand both research and service. Membership in the foundation of the corporation is to consist of three classes: founder members, sustaining members and public members. There shall be one annual meeting of the corporation.

LATIN AMERICA

Committee for Medical Defense.—The Medical Federation of Cuba recently formed a committee on medical defense with Dr. Pedro L. Farinas Mayo, Havana, Cuba, as director. A meeting was held January 23 by Drs. Moisés Chediak, Havana, on "National Organization of Departments for Blood Transfusion," and Guillermo López Roviroso, Havana, on "Importance of Establishing Laws for Food Rations in Any Possible Difficulties."

Deaths in Other Countries

Sir Henry Britten Brackenbury, chairman of the council of the British Medical Association; from 1915 to 1924 chairman of the Insurance Acts Committee and until 1927 chairman of its representative body; member of the General Medical Council and of the advisory committee to the Ministry of Health; practiced general medicine from 1892 to 1927; mayor of the borough of Hornsey, 1895-1896, and alderman till 1930; died at his home in Yeovil, Somerset, England, March 10, aged 76.

Government Services

Mobile Unit Used in Industrial Hygiene Service

The mobile unit of the Division of Industrial Hygiene of the National Institute of Health has just completed a survey covering fifteen plants and eight states. The five plants surveyed in Alabama top the number for any individual state. Three plants in Arkansas were included, two in Louisiana and one each in Mississippi, West Virginia, Kentucky, Oklahoma and Tennessee. A physician and an engineer were in charge of the survey.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Feb. 14, 1942.

An Official Medical History of the War

The work of compiling an official medical history of the war has begun. An editorial board under the chairmanship of the president of the board of education and composed of representatives of the fighting services, the Ministry of Health, the Department of Health of Scotland, the Committee of Imperial Defense and the Medical Research Council has been set up by the war cabinet to direct the preparation of a medical history of the war. This board will have the active collaboration of authoritative bodies and experts. They have met and discussed the scope and plan of the undertaking, the value of such a record made during the war and the war's contribution to medical science. Sir Arthur MacNalty, recently chief medical officer of the Ministry of Health, has been appointed editor in chief, and representatives have been appointed by the service departments concerned. The collection and classification of material has already begun. Much material on medical wartime problems exists and, of course, will grow as the war progresses. The editorial board hopes for the full support and cooperation of the medical profession and requests copies of published articles, reports and other information from health officers and physicians which may be of use in assembling material for the medical historians. They are invited to send it to the Editor in Chief, Medical History of the War, Room 208, Caxton House West, Tothill Street, London, S.W. 1.

The Sprue Syndrome

In *Guy's Hospital Reports* Sir Arthur Hurst describes an important advance which unifies the pathogenesis of the two sprue diseases and celiac disease. He points out that three constant and characteristic features are common to sprue, nontropical sprue and celiac disease and they require explanation in any theory explaining their pathology: 1. The stools contain an excess of split fat but no excess of neutral fat, meat fibers or starch, and no inflammatory material. 2. Roentgenography shows disappearance of the normal feathery or herring bone aspect of the duodenum and jejunum due to the valvulae conniventes. 3. No pathologic changes are found in the intestine after death if postmortem changes have been prevented. Under adequate treatment normal absorption of fat is restored with normal roentgenographic appearances. Hurst therefore concludes that tropical sprue, nontropical sprue and celiac disease are varieties of the same disorder—"the sprue syndrome"—and differ only in the part of the world in which the disease originates and the age of the patient. The characteristic features of the sprue syndrome are the result of paralysis of the muscularis mucosae, which would lead to loss of the pumping action of the villi, by means of which fat is conveyed from the lacteal radicles of the villi into the larger lacteals and to flattening of the valvulae conniventes without changes in normal appearance of the mucous membrane. Paralysis of the muscularis mucosae may be secondary to loss of the normal stimulant of Meissner's (submucosal) plexus or to the effect of vitamin deficiency or some toxemia on the plexus. An exception must be made for those cases of the sprue syndrome associated with disease of the mesenteric glands. Here the hindrance to fat absorption occurs at the level of the mesenteric glands instead of in the villi.

The Danish physician T. E. H. Thaysen previously (1932, 1935) gave good reasons for regarding sprue, nontropical sprue and celiac disease as varieties of the same disease. Celiac disease differs from sprue only in showing characteristics

depending on its occurrence in young and growing children. There is no difference between celiac disease in European children whether it develops in the tropics, when it is likely to be called sprue, or in Europe, or between tropical and so-called nontropical sprue. As Thaysen has pointed out, the tendency to regard diseases more common in the tropics as differing fundamentally from similar ones occurring in nontropical countries is quite unjustifiable. It has gradually been recognized that true beriberi occurs in England and even in Iceland and Newfoundland as well as in hot climates whenever the essential dietetic deficiency is present. The same holds for pellagra, which was long regarded as a purely tropical disorder. Thaysen gave the name idiopathic steatorrhea to the group of diseases comprising sprue, nontropical sprue and celiac disease. But this does not give any indication that the steatorrhea consists in the excretion of split fat in the excretion form of fatty acids and soaps and not of neutral fat.

Canadian Orthopedic Unit for Scotland

An appeal to Canada to send an orthopedic unit for service in the Scottish emergency hospitals has met with a prompt response. Nine Toronto orthopedists and twenty-two nurses experienced in orthopedic work and chosen from all parts of the dominion have arrived with the latest contingent of Canadian soldiers. They brought some special equipment, the gift of the Canadian Red Cross Society, which, with the Canadian Medical Association, organized the unit. The unit is led by Dr. Le Mesurier of the Toronto Sick Children's Hospital and Miss A. B. Hunter, who was matron at Port Arthur General Hospital. Dr. Andrew Davidson, chief medical officer for Scotland, who welcomed the unit, said that before the war Scotland had inadequate provision for orthopedic surgery; now it had the makings of a first class scheme not only for the present emergency but for the postwar period.

The Vitamin D Added to Margarine to Be Doubled

In the last great war the margarine, which then, as now, largely replaced butter, left much to be desired. It was not vitaminized and had a vile taste. Now the taste is so good that few can distinguish it from butter, which it is claimed to equal in vitamin content. It is announced that the amount of vitamin D added to margarine is to be doubled and that in future an ounce will contain more of the vitamin than an average egg. Vitamin D is specially important for children because of its part in the forming of bones and teeth. The other principal sources of vitamin D are eggs and cod liver oil. Increasing advantage is being taken of the free distribution of the oil. But whether the addition of synthetic vitamins to margarine makes it equal to butter has been questioned by Prof. J. C. Drummond, scientific adviser to the Ministry of Food, as stated in a previous letter. He holds that our knowledge of vitamins is still imperfect, that there may still be factors in our natural foods besides those which are replaced by synthetic vitamins.

Acute Hemorrhagic Pancreatitis as a Cause of Sudden Death

The symptoms of acute pancreatitis are generally compared to those of perforation of the stomach or intestine, but the shock and pain are stated to be even more intense. Yet, while sudden death is recognized as a rare result of perforation, this is unmentioned in the textbook descriptions of acute pancreatitis and does not appear to have been reported in British journals previously. Dr. J. F. Gaskell, physician to Addenbrooke's Hospital, Cambridge, has recorded in the *Clinical Journal for January 10* cases of sudden death due to acute hemorrhagic pancreatitis which have come under his observation since December 1932 in necropsies performed by order of the coroner. The subjects were apparently in normal health within two hours of being found dead, except when death had taken

place in bed at night. The evidence that acute pancreatitis was the cause of the sudden death is the condition of the pancreas, with failure, except in one case, to discover any other possible cause. The pancreas was softer than normal and showed hemorrhages in its substance round the ducts and vessels. Fat necrosis was found microscopically, but the macroscopic evidence was slight, which Dr. Gaskell explains by the fact that the death was too sudden to allow it to develop. How dramatic the cases were in their suddenness is shown by the case of a Cambridge undergraduate aged 22, who went on a hare and hound run almost directly after a heavy meal. He stopped about a mile away and bent forward with his hands on his abdomen. He sat in a hedge and was left by a friend, who thought that he was winded. Others in the run coming up later found him dead. The necropsy showed acute hemorrhagic pancreatitis. The pancreas was swollen and tinged pink throughout and microscopically was entirely necrosed with hemorrhages round the vessels.

Streptococcic Cross Infection in Hospital Wards

Recently the danger of wounds becoming infected in hospital wards has been recognized. At a meeting of the Section of Surgery of the Royal Society of Medicine the president, Mr. E. Rock Carling, said that surgeons had been slow in appreciating the work on cross infection done by physicians in hospitals for infectious diseases but that shortly before the war much work was done in wards and operating rooms in the study of the bacterial content of the air and in attempts to sterilize the air by aerosols or ultraviolet rays. Some of the results were startling. Perhaps it was not surprising that in the course of bronchoscopy bronchial flora should in a few minutes be recovered from a distant part of the operating room, but it was surprising that air hitherto entirely free from *Bacillus pyocyaneus* should be found to contain it within five minutes of opening an abscess in which it was present. After Dunkirk surgical literature became full of more extended investigations, and a group of pathologists put forward a new technic for war dressings (*THE JOURNAL*, Nov. 15, 1941).

Prof. A. A. Miles said that the organism commonly concerned in cross infection in wards, *Streptococcus pyogenes*, was most easily traced. It was not the commonest cross infecting organism but, owing to its pathogenicity, the most important. In the peacetime surgical ward the streptococcus reservoir was mainly in the upper respiratory tract. In war additional reservoirs were wounds infected before admission, and hospital infection was more common. The three main channels of infection—dust, droplets and hands and instruments—demanded separate precautions. They could be divided into those in the technic of wound dressing and those apart from it. An improved "no touch" technic with rigid separation of the duties of the dressing team and special precautions against the carrying of infection from bed to bed had substantially reduced hospital infection.

Prof. J. Paterson Ross described the essentials of good technic as follows: 1. Precautions against contamination by dust: bed making to be completed an hour before dressings began; lids for dishes and buckets; wounds to be exposed for only a minimum time. 2. Precautions against contact infection: fingers never to touch a wound, skin around or dressings next the skin; forceps to be used or gloves worn; hands and instruments to be dry. 3. Methods of sterilization: instruments and accessories for dressing to be sterilized by effective methods; cleaning of baths to be beyond reproach.

Dr. M. van den Ende said that bacteria were carried through the air in droplets or dust particles. Large droplets carrying infective doses had a relatively short range and fell to the ground rapidly. Adequate bed spacing and masking was the most effective method of dealing with them. Dry dust borne organisms were distributed into the air in large numbers during

bed making and floor sweeping and might remain suspended for long periods. They could be reduced by treating floors and bedclothes with dust laying oils.

Sir James Walton said that in this war, in contrast to the last war, there had been little experience with gross infections. Bomb lacerations were operated on as soon as the patients got over the shock. If possible, the wounds were sewn up and a dressing was put on which was not removed for ten days, and then complete healing was found. If the wounds were large they were packed with petrolatum gauze, which was not touched for three or four days. Ever since the last war he had been teaching that dressers should use only forceps and should touch nothing with the hand.

London's Underground Railway as a Refuge

Remarkable figures are given of the part played by London's underground railway system as a place of refuge from air raids. During 1941, sixteen million people were given shelter at seventy-nine underground stations. Eight and a half miles of three tier bunks were installed on platforms and subways. Canteens for the refugees were provided, and 11 tons of food was distributed nightly during the raids. Other war measures were also taken by the Transport Board. Three hundred and eighteen thousand four hundred yards of netting was put on vehicle windows to protect passengers from glass broken by blast. Nine thousand five hundred women workers displaced men on the railway. Two thousand three hundred allotments of 80 acres were cultivated for the growing of food by the railway employees.

RIO DE JANEIRO

(From Our Regular Correspondent)

Jan. 25, 1942.

Medical Advertising Regulated by Law

There is no medical association in Brazil with the significance and functions corresponding to those of the American Medical Association in the United States. There are many local medical societies, and in Rio de Janeiro there is the National Academy of Medicine; but a system of affiliation of the local associations into a central national organization is completely lacking. In a country larger than continental United States and insufficiently provided with means of communication, these local medical societies are completely separated from one another. Thus there is no uniformity of policies, no ideas in common, and in certain cases there is even some antagonism. The lack of a central professional body to establish policies explains the diversity of attitudes of separated groups of physicians, the variable behavior of the practitioners and the diversified ethical codes which they follow. Consequently it is not uncommon for many physicians to indulge in extensive advertising, use academic and professional titles to which they are not entitled, try to deceive patients with promises of cure that cannot be fulfilled, and boast special systems of medicine that in some instances border on quackery.

To remedy this situation, federal legislation has been enacted attempting to regulate medical advertising. This act forbids physicians to advertise (1) the cure of certain diseases for which there is no established treatment, (2) treatments aiming to control or to interrupt pregnancy, (3) the practice of more than two medical specialties, (4) treatments through correspondence and newspapers or over the radio, (5) the practice of a medical specialty not included in the curriculum of medical schools and the reference to methods of diagnosis and of treatments not yet recognized by the medical societies, (6) the practice of nonpaid consultations in private offices, (7) discrediting references to systems of medicine and to therapeutic procedures recognized by the present legislation and (8) testimonials or statements from patients certifying the cure of diseases for which there is no established treatment. The act permits the physician to

advertise his academic and scientific titles or real professional qualifications, the price of his services and a general reference to the resources and appliances he uses, as x-rays, radium or medical electricity. It is also permissible to use the press or the radio to discuss medical and health problems in a general manner, without the character of individual treatment. Another section of the same act is intended to control the exaggerations used in the advertising of "patent medicines" and proprietary drugs. It is forbidden to advertise these drugs in the lay press (1) without the declaration "to be sold only under medical prescription" if this condition has been imposed in the licensing of the drug, (2) with the claim to cure tuberculosis, syphilis, cancer or blennorrhagia, (3) with the support of statements from lay patients that they have been cured, (4) with the claim to control or to interrupt pregnancy, (5) with discrediting references to the climate or to the sanitary conditions of the country and (6) with pictures to exhibit physical deformities or obviously faked illustrations to deceive the public.

Leprosy in Brazil

Leprosy is an important health problem in Brazil, because of the large absolute number of cases and the slightly increasing trend. The earliest reference to the disease in this country is from Sa Menezes in 1696. Saint-Hilaire described cases of leprosy in 1820 in the state of Minas Gerais. Prior to 1920 there was no special organization to combat leprosy in Brazil. In that year Carlos Chagas created the division of leprosy in the Brazilian Public Health Service, and Prof. Eduardo Rabello was put in charge of that division. At that time about 20,000 cases of leprosy were supposed to exist in Brazil. The first work of the new division of leprosy was to establish centers of diagnosis throughout the country. Ten years later the number of lepers was estimated by Rabello and Silva Araujo to be about 30,000. Dr. Ernani Agricola, now in charge of the division of leprosy, estimates that the present number of lepers is at least 45,000, or about 100 per hundred thousand of population. According to the leprologist Muir, in the whole world the bulk of the patients are in Asia and Africa (China 1 million, India 1 million, Africa about half a million). The prevalence of leprosy in Brazil is comparable to that of Russia, which has about 170,000 lepers to 170 million of population. The most recent statistics place the number of lepers in the Americas at below 100,000. The estimated distribution is, however, most irregular, and the figures are repeatedly being revised upward.

There are now sixteen modern leprosariums in Brazil, where 15,173 patients were isolated, Dec. 31, 1941. In the state of São Paulo more than 90 per cent of the contagious cases are isolated in six leprosariums. About 2,500 cases are isolated in the state of Minas Gerais and about 1,000 in the state of Para. There are fifteen preventoriums where nondiseased children of lepers are interned, and many more institutions are in course of organization. Many centers of treatment are in operation, where chaulmoogra oil is used extensively. Since 1938 the technic of infiltration of the lesions, through multiple local injections of chaulmoogra oil, has been increasingly used, with promising better results. The raw chaulmoogra material has been imported from India, and the chemical division of the Oswaldo Cruz Institute refines this material and prepares three different kinds of chaulmoogra derivatives. The Brazilian personnel of the institute has been trained by an American specialist, Dr. Howard Cole. The institute is trying to prepare therapeutic material from Brazilian plants of the genus *Hydnocarpus*. Extensive studies on the biology of the leprosy bacillus have been carried out in the Oswaldo Cruz Institute by Dr. H. C. Souza Araujo, who knows the problem of leprosy from direct observation in about forty countries of the world. The epidemiology of leprosy in Brazil is also now under investigation. About 25 per cent of the cases are of the pure nervous form. The disease is more prevalent in males than in females, and

also more prevalent in colored natives than in white Brazilians. The prevalence is higher in white foreign people and in white foreign born Brazilians than in white native born Brazilians.

Brazilian Council of Ophthalmology

As a result of the decision of the fourth Brazilian Congress of Ophthalmology, held in Rio de Janeiro in July 1941, the Brazilian Council of Ophthalmology has been founded. The chief functions of the council are (1) to promote the development and progress of the specialty in Brazil and to establish standards of fitness to practice ophthalmology, (2) to act as preceptors for prospective students of ophthalmology and (3) to arrange and conduct examinations to test the qualifications of those who practice ophthalmology and desire a certificate to prove that they meet the standards established by the council. The council will be formed by the professors of ophthalmology from the medical schools of Rio de Janeiro, São Paulo, Bahia, Porto Alegre, Recife and Bello Horizonte and the presidents of the Brazilian Association of Ophthalmology and of four other state ophthalmologic associations. There will be a central executive board and a regional board in each one of the twenty states of Brazil. Examinations will be held annually and will include the applicant's professional and ethical record (at least two years of private practice), at least twenty case reports and a written examination. The constitution of the council permits, as an introductory measure, that the certificate be issued, up to June 30, 1942, to the physicians who prove that they have had a private practice of ophthalmology of at least five years, or at least two years of practice if they prove the completion of an internship of ophthalmology of not less than one year, or to the physicians who are at present ophthalmologists of hospitals, of clinics and of federal, state or municipal health organizations.

Marriages

MERVYN SHOOR, Lieutenant (j. g.), Medical Corps, U. S. Navy, to Miss Enid Olivi of San Francisco, at Mare Island, Calif., Oct. 25, 1941.

ANGUS CRAWFORD RANDOLPH, Lynchburg, Va., to Miss Marjorie Armstrong McLernon of San Antonio, Texas, Dec. 20, 1941.

HAWLEY HOWARD SEILER, Paia, Maui, Hawaii, to Mlle. Marie Augusta Schreiber of Paris, France, Oct. 4, 1941.

RALPH SILER MORGAN, Durham, N. C., to Miss Ruth Evelyn Dodd of Asheville in Arden in December 1941.

RICHARD A. FORNEY, Rochester, Minn., to Miss Margaret Magel of Twin Falls, Idaho, Aug. 28, 1941.

IGNATIUS W. MADURA to DR. EDITH EASON, both of Chicago, at North Bend, Neb., Dec. 20, 1941.

CLEMENT W. BYRNES to Miss Nona Jane Moore, both of Dunlap, Iowa, in St. Louis, Dec. 23, 1941.

ANTHONY RALPH MARICANO, Brooklyn, to Miss Marion Elizabeth Hobbs of Macon, Dec. 25, 1941.

PHILIP CARY WHITEHEAD, Chatham, Va., to DR. BETTY GORDON WILLIS of Culpeper, Dec. 25, 1941.

FREDERICK MARTIN GRAHAM to Miss Elizabeth Braasch, both of Rochester, Minn., Nov. 15, 1941.

ARTHUR C. LAWRENCE, Lincoln Park, N. J., to Miss Evelyn H. Abrash of Paterson, Nov. 30, 1941.

EDMOND H. KALMON JR., Albany, Ga., to Miss Marion Binkley at Nashville, Tenn., Dec. 2, 1941.

MASON C. SMITH, Meriden, Miss., to DR. ELVIRA A. CORRALES of Tampa, Fla., Dec. 29, 1941.

ARTHUR F. GRANDINETTI, Davenport, Iowa, to Miss Rose Tomlin of Waterloo, Dec. 29, 1941.

WILLIAM M. KUNTZ, Columbus, Ohio, to Miss Mertes Mudd of Waco, Texas, Dec. 30, 1941.

GEORGE C. MCCALLUM, Portland, Ore., to Miss Ruth Waind of McMinnville, Dec. 27, 1941.

ROBERT HAYTER, Dallas, Ore., to Miss Joan Schuyler of Tacoma, Wash., Dec. 5, 1941.

Deaths

Frank Frazier Hutchins, Indianapolis; Medical College of Indiana, Indianapolis, 1892; member of the Indiana State Medical Association and the National Committee for Mental Hygiene; instructor at the Butler University Medical Department and the Indiana Medical College from 1892 to 1895; assistant professor of psychology and psychiatry at the Central College of Physicians and Surgeons from 1903 to 1905; professor of mental and nervous diseases at the State College of Physicians and Surgeons from 1906 to 1908; professor of mental and nervous diseases at the Indiana University School of Medicine from 1908 to 1937 and since 1937 emeritus professor; served as a lieutenant colonel during World War I; at one time medical director and superintendent of the Marion (Ind.) National Sanatorium; formerly chief of the neuropsychiatric service at the Walter Reed General Hospital in Washington, D. C.; clinical director of neuropsychiatry at the United States Veterans' Bureau from June 1922 to July 1923, and formerly dean of the school of neuropsychiatry; colonel in the medical reserve corps of the United States Army; consultant to the City Hospital, Robert W. Long Hospital and the James Whitcomb Riley Hospital for Children; aged 71; died, February 22, in the Methodist Hospital of cerebral hemorrhage.

Martha Tracy * Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1904; since 1940 assistant director of public health of Philadelphia; was associated with her alma mater since 1907 as associate professor and director of the laboratory of physiologic chemistry from 1907 to 1913, professor of physiologic chemistry from 1913 to 1921, professor of hygiene from 1921 to 1923, professor of preventive medicine from 1923 to 1931, dean from 1917 to 1940 and since 1940 emeritus dean; worked with the research department of experimental pathology at Cornell University Medical College, New York, from 1904 to 1907, and for many years under the Huntington Fund for Cancer Research, New York; formerly a member of the board of health of Philadelphia and director of the Philadelphia health council and tuberculosis committee; fellow of the American College of Physicians and of the College of Physicians of Philadelphia; past president of the American Medical Women's Association; in 1917 was awarded the doctor of public health degree from the University of Pennsylvania, Philadelphia; aged 65; died, March 22, in the Hospital of the Woman's Medical College of pneumonia.

James Addison Price * Memphis, Tenn.; Atlanta (Ga.) College of Physicians and Surgeons, 1912; past president of the Tennessee Tuberculosis Association; formerly vice president of the National Tuberculosis Association; served during World War I; at one time assistant professor of medicine at the University of Tennessee College of Medicine; superintendent of the Irene Byron Sanatorium, Fort Wayne, Ind., from 1919 to 1921; from 1921 to 1941 medical director of the Oakville (Tenn.) Memorial Sanatorium; was on the staffs of the Methodist Hospital, John Gaston Hospital and the Baptist Memorial Hospital, where he died, January 10, of cerebral hemorrhage, aged 54.

Harry Arthur Paskind * Chicago; University of Illinois College of Medicine, Chicago, 1920; associate professor of nervous and mental diseases at Northwestern University Medical School; member of the American Neurological Association, Association for Research in Nervous and Mental Diseases and the Central Neuropsychiatric Association; president of the Chicago Neurological Society, 1940-1941; served during World War I; editor of the psychiatric section of the *Year Book of Neurology, Psychiatry and Endocrinology* from 1934 to 1938; aged 45; attending neurologist, Evanston (Ill.) Hospital, where he died, March 24, of bronchiectasis and cardiac hypertrophy.

Arnold R. Miller, Harrisville, Mich.; Detroit College of Medicine, 1906; member of the Michigan State Medical Society; past president of the Alpena County Medical Society; for many years mayor of Harrisville; member of the board of education; chairman of the Civilian Defense Council and an examiner for the county draft board; at one time acting assistant surgeon in the United States Public Health Service; owner of a hospital bearing his name; aged 59; died, February 22, of injuries received in an automobile accident.

R. Andral Bratton, York, S. C.; Medical College of the State of South Carolina, Charleston, 1884; member of the South Carolina Medical Association; past president of the York County Medical Society; formerly member of the state board

of medical examiners; for many years a member of the board of trustees of the city schools; on the visiting staff of the York County Hospital, Rock Hill; aged 82; died, January 26, of arteriosclerosis.

Harry Louis Pollock * Chicago; College of Physicians and Surgeons of Chicago, 1894; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; head of the department of otolaryngology, American Hospital; on the staff of the Walther Memorial Hospital; aged 67; died, January 24, in Los Angeles.

Alfred Jones Drury * Roselle, N. J.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1923; member of the Medical Society of New Jersey; on the staffs of the Elizabeth General Hospital and St. Elizabeth Hospital, Elizabeth, N. J., and the Rahway (N. J.) Hospital; physician for the public schools; aged 44; died, January 24, of coronary thrombosis.

Nathan Goodfriend * New York; Columbia University College of Physicians and Surgeons, New York, 1902; fellow of the American College of Surgeons; attending ophthalmologist, Bronx Hospital, and secretary of its medical board; assistant surgeon, Manhattan Eye, Ear and Throat Hospital; aged 61; died, January 17, of coronary thrombosis.

Frank Edgar Fee * Cincinnati; Medical College of Ohio, Cincinnati, 1895; professor emeritus of clinical surgery at the University of Cincinnati College of Medicine; fellow of the American College of Surgeons; visiting surgeon, Christ Hospital; consulting surgeon, Cincinnati General Hospital; aged 68; died, January 29, of coronary occlusion.

Ambrose Watts Thrush, Chambersburg, Pa.; Jefferson Medical College of Philadelphia, 1890; member of the Medical Society of the State of Philadelphia; secretary and past president of the Franklin County Medical Society; formerly county coroner; aged 76; on the staff of the Chambersburg Hospital, where he died, January 28, of pneumonia.

W. Kempton Browning, Merchantville, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1897; member of the Medical Society of New Jersey; served as medical inspector in the schools of Camden and Merchantville; aged 67; died, January 22, in the Cooper Hospital, Camden, of coronary occlusion and lobar pneumonia.

Charles Harkness Willits, Miami, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1879; medical director of the Provident Mutual Life Insurance Company in Philadelphia; aged 84; died, January 2, of aortic stenosis and chronic cystitis.

Bertrum Brant McElhany * Youngstown, Ohio; Western Reserve University Medical Department, Cleveland, 1900; on the consulting staff of St. Elizabeth Hospital; aged 69; died, January 13, in the Youngstown Hospital, Southside Unit, of injuries received when struck by an automobile as he was crossing the street.

Oat Whitney * Adrian, Mich.; Michigan College of Medicine and Surgery, Detroit, 1894; past president and secretary of the Lenawee County Medical Society; on the staff of the Emma L. Bixby Hospital; aged 73; died, January 7, in the Harper Hospital, Detroit, of primary splenic anemia and pyelonephritis.

Frederick Chalfonte Peters, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1911; served during World War I; since 1939 professor and head of the department of ophthalmology at his alma mater; aged 54; died, January 7, in the Hahnemann Hospital of intracranial hemorrhage.

David Arthur Morgan, Memphis, Tenn.; Barnes Medical College, St. Louis, 1905; served during World War I; at one time on the staff of the United States Veterans Hospital, Excelsior Springs, Mo.; aged 58; died, February 23, in the Baptist Memorial Hospital of cerebral hemorrhage.

John Adams Miller, Roscoe, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1887; member of the Medical Society of the State of New York; for many years county coroner; aged 79; died, January 17, in Monticello of chronic myocarditis.

Samuel Mathew McLaughlin, Santa Monica, Calif.; Eclectic Medical Institute, Cincinnati, 1899; served during World War I; aged 68; was shot and killed, January 18, when he was driving past an aircraft plant and the gun of a soldier who was on guard was accidentally discharged.

Gertrude Anna Spriggs, Lomita, Calif.; College of Physicians and Surgeons of San Francisco, 1900; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the California Medical Association; aged 77; died, Dec. 30, 1941.

Daniel Crumlish Handley, Cincinnati; Cincinnati College of Medicine and Surgery, 1897; member of the Ohio State Medical Association; at one time county and deputy coroner; served during World War I; aged 73; died, January 30, in Christ Hospital of uremia.

Charles Joseph Jaquish, Houston, Texas; University of Pennsylvania School of Medicine, Philadelphia, 1920; member of the State Medical Association of Texas and of the American Academy of Ophthalmology and Otolaryngology; aged 50; died, Dec. 24, 1941.

Charles Hayes King, Bucyrus, Ohio; Ohio Medical University, Columbus, 1906; member of the Ohio State Medical Association; past president and secretary of the Crawford County Medical Society; aged 63; died, January 29, of cerebral hemorrhage.

Henry John Niebruegge, St. Louis; St. Louis College of Physicians and Surgeons, 1900; member of the Missouri State Medical Association; on the staff of the Deaconess Evangelical Home and Hospital; aged 68; died, January 13, of heart disease.

Peter Albert Trice, Thomasville, Ala.; Louisville (Ky.) Medical College, 1902; member of the Medical Association of the State of Alabama; aged 67; died, January 14, in the Goldsby King Memorial Hospital, Selma, of cerebral hemorrhage.

George Francis Pierrot Ⓢ Seattle; American Medical College, St. Louis, 1889; St. Louis College of Physicians and Surgeons, 1890; formerly health officer of Wahkiakum County, Wash., and Eldorado County, Nev.; aged 80; died, Dec. 9, 1941.

Watson Fuller Wood, White Church, Kan.; University Medical College of Kansas City, Mo., 1891; member of the Kansas Medical Society; aged 81; died, January 20, in the Bethany Hospital, Kansas City, of cerebral hemorrhage.

Thomas Shaw Webster, Toronto, Ont., Canada; Victoria University Medical Department, Coburg, 1888; University of Toronto Faculty of Medicine, 1889; one of the founders of the Toronto Western Hospital; aged 84; died, Dec. 30, 1941.

David Herman Fuller, Fall River, Mass.; Jefferson Medical College of Philadelphia, 1904; formerly medical director and superintendent of the Fall River General Hospital; aged 61; died, January 31, in Westboro of meningoencephalitis.

Ernest Lafayette Handley, Pocahtontas, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1920; member of the Arkansas Medical Society; formerly county coroner; aged 48; died, Dec. 9, 1941, in a hospital at Jonesboro.

Henry Albert Pfeifer, Milwaukee; Wisconsin College of Physicians and Surgeons, Milwaukee, 1909; member of the State Medical Society of Wisconsin; aged 59; died, January 12, in St. Joseph's Hospital of cirrhosis of the liver.

Edward M. Harris, Cushing, Okla.; Chattanooga (Tenn.) Medical College, 1901; member of the Oklahoma State Medical Association; aged 69; died, January 26, in the Oklahoma City General Hospital of diabetes mellitus and thrombosis.

Emerson Meadows Cooper, Rockwood, Mich.; Trinity Medical College, Toronto, Ont., Canada, 1900; member of the Michigan State Medical Society; aged 65; died, January 29, in the University Hospital, Ann Arbor, of uremia.

Lafayette Franklin Shoemaker, Hillsboro, Texas; Medical College of Alabama, Mobile, 1902; member of the State Medical Association of Texas; aged 73; died, Dec. 22, 1941, in a hospital at Temple of cerebral hemorrhage.

Albert Louis Gustetter Ⓢ Tucson, Ariz.; Medical College of Ohio, Cincinnati, 1900; past president of the board of medical examiners; veteran of the Spanish-American and World wars; aged 65; died in January of pneumonia.

Frank Terry Brooks, Palma, Majorca, Spain; Long Island College Hospital, Brooklyn, 1893; aged 73; died, January 12, in the Hospital of the Good Samaritan, Los Angeles, of arteriosclerosis, heart disease and diabetes mellitus.

Walton Wheeler Young, Washington, D. C.; Howard University College of Medicine, Washington, 1921; aged 65; died, January 6, in the Eastern Dispensary and Casualty Hospital of myocarditis and arteriosclerosis.

Lincoln Jay Pierce, Brookfield, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1913; member of the Missouri State Medical Association; aged 56; died, January 22, of mesenteric thrombosis.

Donald John Macdonald, Halifax, N. S., Canada; McGill University Faculty of Medicine, Montreal, Que., 1897; served during World War I; fellow of the American College of Surgeons; aged 69; died, Dec. 19, 1941.

Joseph J. Shafer Ⓢ Louisville, Ky.; Southern Medical College, Atlanta, 1897; member of the American Academy of Ophthalmology and Otolaryngology; aged 70; died, January 4, in St. Anthony's Hospital of pneumonia.

R. J. Clower, Morven, Ga.; Atlanta Medical College, 1895; member of the Medical Association of Georgia; aged 68; died, January 12, in the Brooks County Hospital, Quitman, of coronary occlusion and chronic nephritis.

Francis Marion Thurmon, Pearl, Ill.; Barnes Medical College, St. Louis, 1904; member of the Illinois State Medical Society; formerly mayor and member of the school board; aged 69; died, January 14, of uremia.

William W. Long, Sulphur Springs, Texas; Memphis (Tenn.) Hospital Medical College, 1901; member of the State Medical Association of Texas; aged 71; died, January 11, in Dallas of coronary sclerosis.

Andrew Hunter Ⓢ McKeesport, Pa.; Medico-Chirurgical College of Philadelphia, 1891; served during World War I; on the staff of the McKeesport Hospital; aged 72; died, January 23, of hypernephroma.

Frederick Kent Ream, Palm Beach, Fla.; Rush Medical College, Chicago, 1892; also a dentist; aged 72; died, January 18, in the Good Samaritan Hospital, West Palm Beach, of a self-inflicted bullet wound.

John H. O'Dell, Three Rivers, Mich.; Detroit College of Medicine, 1903; member of the Michigan State Medical Society; on the staff of the Three Rivers Hospital; aged 63; died, January 29, of pneumonia.

Norman Paul Hersam Ⓢ Stoneham, Mass.; Harvard Medical School, Boston, 1912; school physician; aged 57; died, January 15, in the Middlesex County Sanatorium, Waltham, of military tuberculosis.

Sidney Bruce Matthews, Winnfield, La.; Memphis (Tenn.) Hospital Medical College, 1911; aged 68; died, January 18, in a hospital at Shreveport of arteriosclerosis and hypertensive cardiovascular disease.

Moses Lot Haning, Browning, Mo.; St. Louis University School of Medicine, 1903; member of the Missouri State Medical Association; aged 63; died, January 9, in Muskogee, Okla., of coronary occlusion.

Fred V. Watson Ⓢ Los Angeles; Marion-Sims College of Medicine, St. Louis, 1899; on the staff of the Presbyterian Hospital-Olmstead Memorial; aged 65; died, January 6, of cerebral hemorrhage.

Charles Terrel Hughes, Gainesville, Texas; Kentucky School of Medicine, Louisville, 1889; member of the State Medical Association of Texas; aged 81; died, January 15, of cerebral hemorrhage.

Anthony Lothar Fink, Carroll, Iowa; Deutsche Universität, Medizinische Fakultät, Prague, Austria, 1910; on the courtesy staff of St. Anthony Hospital; aged 60; died, January 20, of chronic myocarditis.

Myer Jerome Herschman Ⓢ Washington, D. C.; George Washington University School of Medicine, Washington, 1917; member of the American Urological Association; aged 47; died, Nov. 15, 1941.

George Robert Norman, Tulsa, Okla.; Birmingham Medical College, 1911; member of the Oklahoma State Medical Association; served during World War I; aged 56; died, January 21, of aortitis.

Henry Peronneau Brown, Lynchburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1907; county coroner; aged 58; died, January 29, of shock following an automobile accident.

John B. Legnard, Houston, Texas; Northwestern University Medical School, Chicago, 1902; served during World War I; aged 66; died, January 4, in the Hermann Hospital of coronary occlusion.

Huldah Davis Hurst, Lincoln, Neb.; Lincoln Medical College of Cotner University, 1905; aged 78; died, January 17, in the Medical and Surgical Hospital, San Antonio, Texas, of coronary occlusion.

Harry Fleisher Rentschler, Reading, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; aged 72; died, January 4, of angina pectoris.

William Givin Rhoten, Wooster, Ohio; Medical College of Ohio, Cincinnati, 1900; formerly health officer of Wayne County; aged 67; died in January in Massillon of chronic myocarditis.

Ora Alexander Johnson, Kansas City, Mo.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1897; aged 69; died, January 26, of coronary occlusion and carcinoma of the prostate.

Henry Bernard Hibbe @ Dubuque, Iowa; State University of Iowa College of Medicine, Iowa City, 1922; aged 50; died, January 24, in St. Clare Hospital, Monroe, Wis., of cirrhosis of the liver.

Louis George Cucinotta, Brooklyn; Tulane University of Louisiana School of Medicine, New Orleans, 1931; on the staff of St. John's Hospital; aged 37; died, January 17, of coronary thrombosis.

Mary Elizabeth Burns, Fitchburg, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1910; for many years school physician; aged 59; died, January 27, of coronary thrombosis.

Robert Reid Berry @ Union, S. C.; Medico-Chirurgical College of Philadelphia, 1901; on the staff of the Wallace Thomson Hospital; aged 64; died, January 23, of coronary occlusion.

Harry Jarrett @ Camden, N. J.; Jefferson Medical College of Philadelphia, 1887; aged 75; died, January 29, at his home in Moorestown of injuries received in an automobile accident.

Andrew Sargent, Hopkinsville, Ky.; Louisville Medical College, 1881 and 1883; formerly member of the city council and state legislature; aged 83; died, January 31, of diabetes mellitus.

Albert Franklin Adams, Reno, Nev.; Cooper Medical College, San Francisco, 1904; served during World War I; aged 62; died, January 16, of coronary occlusion and hypertension.

Levi E. Hinshaw, De Ruyter, N. Y.; Dunham Medical College, Chicago, 1902; formerly a lawyer; for many years health officer; aged 77; died, January 21, of pernicious anemia.

Merle S. Boyer, Philadelphia; Medico-Chirurgical College of Philadelphia, 1896; medical director of the National Accident and Health Insurance Company; aged 71; died, Dec. 10, 1941.

George Westveer, Grand Rapids, Mich.; Physio-Medical College of Indiana, Indianapolis, 1898; aged 74; died, January 18, in St. Mary's Hospital of perforating ulcer of the stomach.

Warren Brodie De Jernett, Commerce, Texas; Bellevue Hospital Medical College, New York, 1883; aged 82; died, January 31, in a hospital at Dallas of cerebral hemorrhage.

Alton Bowie Reddick, Sylvania, Ga.; University of Georgia Medical Department, Augusta, 1911; aged 55; died, January 13, in Atlanta following an operation on the lung.

Eliel Grant Myrick, Fairfield, Iowa; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1904; aged 72; died, January 6, of myocardial insufficiency.

Columbus Huffaker, Chrisman, Ill.; University of Louisville (Ky.) Medical Department, 1905; aged 69; died, January 11, in a hospital at Kankakee of chronic myocarditis.

Leo J. Drozniakiewicz, Milwaukee; Milwaukee Medical College, 1907; member of the State Medical Society of Wisconsin; aged 60; January 20, of coronary thrombosis.

Hollie Bascum Wilson, Vicksburg, Miss.; Bellevue Hospital Medical College, New York, 1888; aged 82; died, January 10, of uremia and benign prostatic hypertrophy.

Lee Otis Vickery, Lena, Ill.; Loyola University School of Medicine, Chicago, 1919; member of the Illinois State Medical Society; aged 54; died, January 10, of uremia.

Warford Lash Nixon, Somerville, N. J.; Jefferson Medical College of Philadelphia, 1889; served during World War I; aged 74; died, January 20, of cerebral hemorrhage.

T. N. McMillan, Thomaston, Ala.; Medical College of Alabama, Mobile, 1895; aged 74; died, January 18, in the Baptist Hospital, Selma, of coronary thrombosis.

William F. Decker, Suffern, N. Y.; New York Homeopathic Medical College, New York, 1876; aged 86; died, January 25, in Newburgh of cerebral hemorrhage.

Gilbert Leonard Hagen, Minneapolis; Minneapolis College of Physicians and Surgeons, 1904; aged 83; died, January 27, of cardiac decompensation and hypertension.

James Oscar Hicks @ Victoria, Texas; Kentucky School of Medicine, Louisville, 1906; aged 61; died, Dec. 31, 1941, in the Victoria Hospital of diabetes mellitus.

John A. Pollard, Lynchburg, Va.; University of Louisville (Ky.) Medical Department, 1894; aged 68; died, January 24, of mitral stenosis and coronary thrombosis.

Alfred H. Tickell, Nevada City, Calif.; Southern Medical College, Atlanta, Ga., 1891; member of the California Medical Association; aged 77; died, January 28.

George Mortimer Wetherell, Adrian, Mich.; Niagara University Medical Department, Buffalo, 1886; aged 84; died, January 3, of cerebral hemorrhage.

Benjamin Lawrence Brigham, Tacoma, Wash.; College of Physicians and Surgeons, Baltimore, 1880; aged 83; died, January 30, of cerebral hemorrhage.

William James Houck @ Newark, N. J.; Medico-Chirurgical College of Philadelphia, 1899; aged 75; died, January 27, of cerebral hemorrhage.

Palmer E. Brandon @ Sioux Falls, S. D.; Northwestern University Medical School, Chicago, 1907; aged 64; died, January 21, of coronary thrombosis.

S. D. Smith, Byron, Ga.; College of Physicians and Surgeons, Baltimore, 1882; aged 85; died, January 3, in a hospital at Macon of bronchopneumonia.

Michael Joseph McAvoy, Baltimore; College of Physicians and Surgeons, Baltimore, 1900; aged 69; died, January 27, of cirrhosis of the liver.

Ocie Rush Peek, Hickory, Miss.; Mississippi Medical College, Meridian, 1907; aged 73; died, Dec. 17, 1941, in the Rush's Infirmary, Meridian.

Houston Rather, Dallas, Texas; Kentucky School of Medicine, Louisville, 1893; aged 80; died, January 15, in Los Angeles of arteriosclerosis.

Frank M. Gallagher @ Columbus, Ohio; College of Physicians and Surgeons, Baltimore, 1901; aged 70; died, January 16, of coronary occlusion.

Paul Acberus Phillips, Springfield, S. C.; Bellevue Hospital Medical College, New York, 1891; aged 72; died, January 23, of heart disease.

John Wesley Moorer, Selma, Ala.; McHarry Medical College, Nashville, Tenn., 1899; aged 62; died, January 12, of cardiac decompensation.

Benjamin Hooke Anderson, Andersonburg, Pa.; Medico-Chirurgical College of Philadelphia, 1899; aged 74; died, January 8, of senility.

Henry John Hunter, Ilion, N. Y.; Baltimore University School of Medicine, 1890; aged 73; died, January 2, of cerebral hemorrhage.

Burwell Wilks Gunn, Maplewood, Mo.; Marion Sims College of Medicine, St. Louis, 1892; aged 78; died, January 30, of myocarditis.

Frank Beemer, Toronto, Ont., Canada; Victoria University Medical Department, Coburg, 1884; aged 79; died, Dec. 12, 1941.

Abram C. Boice, Orange, Calif. (licensed in Indiana in 1897); aged 85; died, Dec. 29, 1941, of chronic myocarditis.

DIED IN MILITARY SERVICE

Benjamin Franklin Norwood @ Medical Director, Captain, U. S. Navy, New York; University of Tennessee College of Medicine, Memphis, 1912; entered the Navy Sept. 24, 1917; surgeon attached to the Naval Medical Supply Depot, Brooklyn; aged 56; died, January 12, of coronary thrombosis.

Adrian Collison Schoedel, Flushing, N. Y.; University and Bellevue Hospital Medical College, New York, 1934; member of the Medical Society of the State of New York; first lieutenant in the medical reserve corps of the United States Army, in the 3d Battalion, 18th Infantry, 1st Division, Fort Devens, Mass.; aged 32; was killed, February 17, in an automobile accident near Acton, Mass.

Bureau of Investigation

"MEDIEVAL RACK" STRETCHES THE TRUTH—NOT THE SPINE

U. S. P. O. Department Catches Up with the Pandiculator

So-called spine stretchers, advertised to increase height, "rejuvenate" or perform some other miracle, are so obviously fraudulent that the Post Office Department has banned one after another from the mails for the protection of the public. One of the early ones to suffer this fate—as long ago as 1914—was "The Cartilage Invention," which was promoted from Rochester, N. Y., by some notorious swindlers whose other medical schemes also were scotched by the Post Office. Other similar devices have been exposed in these pages during the intervening years, including one put out by Clara Louisa Glover and "Bernard Bernard" (real name Trapschuh, himself a short person) from Sausalito, Calif. (see *THE JOURNAL*, July 6, 1929, p. 53). Another similar swindle was the "Stebbing System of Height Increase," originally promoted from London, England, but later from the United States, by Mrs. Daisy Stebbing, along with a "Beautipon Treatment" for putting on weight and the "Slim-cream Method" of reducing.

The latest "spine stretcher" to be branded by the Post Office as a fraud is "The Pandiculator," although it thrived for over thirty years. As long ago as 1914, perhaps earlier, it was being advertised in magazines of the health fad type under such

A typical "Pandiculator" advertisement.

claims as "Grow Tall! Get Well! Be Young . . . No More Rheumatism or Sciatica . . . A Cure for Old Age. It will Increase the Length of the Human Body." Further, it was claimed to have "gained the unqualified approval of the foremost physicians of all schools." Perhaps this meant merely the osteopathic school, for the testimonial of Albert Thurlow Hunt, an Omaha osteopath who later moved to Los Angeles, was especially featured. He put out a preposterous device of his own under the high sounding name "Dr. Hunt's New Cervical Spine Relaxer." This was so obviously fakish that the Post Office debarred it from the mails by means of a fraud order, as detailed in *THE JOURNAL*, Dec. 27, 1941, page 2269.

The few doctors of medicine whom The Pandiculator Company of Cleveland cited as users and endorsers of its device were persons of low professional standing such as Albert Abrams and George Starr White, whose own medicomechanical fakes often have been exposed in these columns. The Pandiculator concern brazenly circularized doctors of medicine with such claims as "Progressive leaders of the medical profession have accepted Pandiculation without reservation . . . There is no danger, no experimentation—Pandiculation is no theory. Practice has proved its merits and the medical profession has approved of its use. It is no fad or novelty which will evaporate over night." Nevertheless, the company deemed it expedient to call the device by different names according to the type of practitioner: "The Traction Couch for Physicians," "The Osteotractor for Osteopaths" and "The Chiro-tensor for Chiropractors." Nor were these various practitioners to have exclusive rights in employing it, for it was also played up "for home use by all the family." If there was any difference among these Pandiculators the theory and operation apparently were the same.

The Pandiculator was not cheap, at least in price, for a doctor of medicine who was solicited by form letter to purchase

one was told that it would cost him \$120—but then, the possession of it, he was informed, "opens the door of opportunity for you" and offered "an opportunity to take your place with leading members of your profession." "Inordinately gullible" would be the accurate substitution for "leading."

But Uncle Sam frequently is skeptical about promises that seem a bit too rosy. On May 29, 1941 the Post Office Department served notice on The Pandiculator Company of Cleveland and its officers to show cause on June 18 why a fraud order should not be issued against it. After the defendants had obtained several continuances the company's secretary, H. C. Crowell, and the firm's attorney appeared at the hearing finally held on August 6. At that time the government charged the Pandiculator Company with using the mails to promote its device by means of false and fraudulent pretenses, representations and promises to the effect that when used as directed it would prevent, overcome and cure "every conceivable condition and physical deficiency" including goiter, rheumatism, angina pectoris, pleurisy, asthma, tuberculosis, pneumonia, hay fever, ulcers, diabetes, Bright's disease, rupture, female disorders, locomotor ataxia and other ailments too numerous to catalogue here. All this regardless of the causes of these disorders or the failure of other methods of treatment to produce such results!

The hearing brought out that the Pandiculator Company was not a corporation in spite of its using the names of persons represented as its "officers"; that its sole owner was the person designated as "secretary," Henry C. Crowell, a Cleveland attorney; that Crowell had purchased the business in 1918 from a David B. Cropp and later had sold it to a Harry L. Spaulding, from whom he had bought it back in 1932, and that since then he had operated it for his sole use and benefit. According to his testimony approximately seven thousand Pandiculators had been sold to the public at prices ranging from \$25 to \$125. Some customers had purchased the device after assurance from the promoters that it would cure them of such diseases as tuberculosis, diabetes and arthritis. Some others had reported to the Post Office that the company neither filled their orders nor refunded their money, or, if it did the latter, it was only after complaint had been made to the Post Office.

According to other evidence presented, the Pandiculator sold to home users was a rectangular shaped box covered with fabrikoid. At the ends were T shaped iron posts, one of which was affixed to the box and the other to an adjustable bar which ran in under the box. To use the device a person had to recline on the box and attach his feet to the adjustable post and his head to the fixed post by means of straps which were part of the mechanism. Then, by turning a wheel on the side, which was attached to a cable threaded through a system of pulleys, the adjustable bar was extended and the body stretched.

An eminent orthopedic surgeon of Washington, D. C., who was called as an expert medical witness for the government testified that he had examined the Pandiculator and was familiar with its action and the effect it would have when used as directed; that this would be a stretching of the body but in only one direction, from head to foot; that spinal deformities caused by tuberculosis, syphilis, arthritis, rickets and infantile paralysis must be considered each on a separate and distinct basis in every instance; that although so-called traction therapy is sometimes used by orthopedists in treating certain diseases of the bones and joints, the direction and weight of the pull required in order to obtain beneficial results therefrom can be obtained only after a thorough examination of the patient by a competent practitioner; and that such examination frequently reveals that traction, even when indicated, must be exerted in an angular direction rather than in a straight line, as with the Pandiculator, and must be applied continuously rather than intermittently, as with this device. The witness also exposed the fallacy of some other representations made for the Pandiculator. The opposing witness was a chiropractor and naturopath.

The general worthlessness of the device for increasing height and curing or even benefiting the numerous ailments mentioned in the advertising was so apparent that a fraud order was issued on Dec. 8, 1941 debarring the Pandiculator Company and H. C. Crowell from the mails. Thus passes—it is hoped—a scheme that has swindled the credulous for many years.

NEW NAMES FOR OLD SWINDLES

Collecting Fraud Orders as a Hobby

Certain individuals against whom more than one Post Office Fraud Order has been issued were exposed under the above title in *THE JOURNAL* for March 7, 1942, p 837. Others of a similar ilk are presented herewith.

"Prof" C A Isbell, Fred Mandeville, V L Mandeville and V L Davis—This department of *THE JOURNAL*, Sept 28, 1940, page 1118, dealt with fraud orders that the Post Office Department had issued against seven concerns for conducting medical swindles through the mails. One of these was operated by a "Prof" C A Isbell of Colfax, Calif., who promoted "Isbell's Mineral" for such disorders as cancer, diabetes, pyorrhea, rheumatism, hemorrhoids, stomach ailments and venereal diseases. And what was this alleged panacea? Just a mixture of iron and aluminum sulfates with minute amounts of silica, phosphate, calcium and potassium. Apparently reluctant to relinquish a profitable piece of quickers, Isbell attempted to evade the fraud order by advising his customers and prospects to send no postal money orders but to remit by checks or express money orders addressed to Fred Mandeville at Colfax, Calif (Isbell's home town), or to V L Mandeville or V L Davis at Wenmar, Calif. But the Post Office again caught up with Isbell and on Feb 7, 1941, extended the 1940 fraud order to cover these Mandeville and Davis names.

Tru-Science, Natur-Tabs Company and Wilbur Hanson—In *THE JOURNAL* Dec 28, 1940, page 2298, there was described in detail a case in which the Post Office Department closed the mails on May 28, 1940 to the Natur Food Company and its officers and agents at Kansas City, Mo. The article showed that this fraud order was supplemental to one that the Department had issued on Feb 1, 1940 against the National Diabetic Food Company, George H Keyes and R Randall for conducting a fraudulent mail order scheme in selling "National Diabetic Food" and a supplementary product, "National Mineral Ration" as an alleged "diabetes cure." After the issuance of the first fraud order the Department discovered that the scheme was being conducted under the name Natur Food Company and hence found it necessary to issue an additional order. Further, the article brought out that National Diabetic Food was a pulverized form of the weed saltbush, and its ash contained traces of calcium, iron phosphate, sodium, potassium and chloride. It was further shown that National Mineral Ration was essentially a mixture of minute amounts of epsom salt, calcium, iron, manganese, ammonia, carbonate, bicarbonate, sulfate, chloride and sulfur, with traces of iodides, bromides and possibly of copper, zinc and lithium. The article included the summary of this case by the Department's solicitor, Judge Vincent M. Miles, in which he said, in part, that although the name "Tru Science" also was used by this Kansas City outfit it did not seem necessary to include it in the fraud order against the Natur Food Company. Not long afterward, however, the Post Office discovered that the swindle was still being promoted by George Keyes assisted by Thelma Randall, the daughter of his original partner, and that they were now operating under the names Tru Science, Natur Tabs Company and Wilbur Hanson, North Kansas City, Mo. On May 23, 1941 the Post Office extended the earlier fraud orders to cover these last three names.

The Health Educational Clinic, R L Fraser, The Clinic of Preparedness and Mildred Hagaman—From McCrory, Ark., Robert Lee Fraser, M D operated a mail order business under the high sounding title "The Health Educational Clinic" and sold something with the equally impressive name, "Heavy Vitamins." The Post Office Department charged that he promoted this nostrum under false and fraudulent pretenses, representations and promises to the effect that when used as directed it would cure, overcome, remove the cause of, and prevent the recurrence of cancer, colitis, eczema, athlete's foot, asthma, lumbago, pyorrhea, diabetes, pneumonia, prostate and bladder disorders, tuberculosis, chronic appendicitis, venereal diseases and some other things, regardless of the cause or severity of any of these conditions! And what was this cure all? According to a government chemist who analyzed it, Heavy Vitamins contained 9.952 per cent by weight of sulfuric acid and 0.005 grain per hundred cubic centimeters of mineral matter the remainder being water. The chemist further testified that he found no organic substances in the preparation. Expert medical evidence produced at the hearing showed that a solution having no organic substances could not contain vitamins, hormones or the amino-acids which Fraser claimed were present in Heavy Vitamins, in spite of his testimony that the product contained all the foods necessary to sustain life, including twenty-two amino acids and a food for every gland in the body. Further, it was reported that Fraser's testimony admitted that he had never personally examined any of the patients whose records he submitted to determine whether or not the alleged improvements in their condition were actual but that he had merely accepted their statements as being correct. As his various claims and representations were found to be unsubstantiated by scientific evidence, the Post Office Department issued a fraud order on June 23, 1941 against the Health Educational Clinic, Dr R L Fraser as manager and founder and the officers and agents of his concern. Not long afterward the Post Office discovered that Fraser had resumed his enterprise and was operating not only under his own name and that of the Health Educational Clinic, but also under two new trade styles, the Clinic of Preparedness and Mildred Hagaman, Secretary. As a precaution, however, he was sending his nostrum out through private express companies and explaining in his letters to customers that he could no longer mail Heavy Vitamins but would have to ship the stuff by express "due to 5th Column interference through the post-office department." The second fraud order, issued against the two new trade styles that Fraser was using, was issued Oct 28, 1941.

AMERICAN BOARD OF PEDIATRICS *Written* Locally, Sept 18. *Oral* Chicago, Nov 23. Final date for filing application is July 1. Sec, Dr C A Aldrich, 707 Fullerton Ave, Chicago.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY *New York* December. Final date for filing application is Oct 1. Sec, Dr Walter Freeman, 1028 Connecticut Ave N W, Washington, D C.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Contracts: Validity of Contract Restricting Right to Practice Optometry.—The plaintiff operated a number of jewelry stores throughout the state of New York and employed the defendant, a licensed optometrist, in the optical department of one of those stores. The defendant's contract of employment, executed in February 1939, contained two specific covenants. The first provided, in substance, that during his employment, or for one year thereafter, the defendant would not engage in any business that competed with the plaintiff within a radius of 10 miles of any city, town or village in which the plaintiff operated a store. The second restrained the defendant, during the same period of time, from divulging any of the plaintiff's trade secrets or soliciting the patronage of any of the plaintiff's customers. On Jan 11, 1940 the defendant resigned from the plaintiff's employ, rather than be transferred to another town, and on Feb 1, 1940 he opened his own office for the practice of optometry in the town in which he had been employed by the plaintiff. The plaintiff therefore filed a suit in the supreme court, Broome County, N Y, to enjoin the defendant from breaching the aforementioned covenants.

Contracts and agreements of this character, said the supreme court, have been enforced when they are not unduly harsh, unreasonable or inequitable. The court, however, held that the contract in this case was much broader in scope than was necessary to protect the plaintiff's interests. The contract in question assured the defendant neither a definite tenure of employment nor a definite wage. He could have been discharged the next day or his wages could have been substantially reduced. The plaintiff already operated stores in many places in the state and might in the future extend such activities to every sizable community. The result of this would be completely to eliminate the defendant from practicing optometry in the state of New York for one full year. Such a result, concluded the court, was inequitable and would be disastrous to a young professional man. The court further held, however, that the provi-

sions of the second restrictive covenant were fair and should be enforced. It would be most unreasonable, the court said, to allow the defendant to steal the plaintiff's customers through a knowledge of their identity gained by him as an employee. The court therefore held in effect that the defendant could maintain his private office but that he could not build up his practice by taking advantage of the acquaintanceships made during his prior employment by the plaintiff.—*Rudolph Bros., Inc. v. Greulich*, 21 N. Y. S. (2d) 971 (N. Y. 1940).

Poisoning: Lead Poisoning of Infant Attributed to Metallic Breast Shields.—The infant plaintiff was born in a New Jersey hospital on June 6, 1936. His mother obtained and used metallic lead nipple shields. Accompanying the shields was a circular describing the history of their development and stating, in part:

For the prevention and cure of sore nipples these shields should be applied as soon after delivery as possible, and in using them the only attention required is to wipe the nipple previously to nursing and apply the shield again immediately afterwards. They are in no way likely to be injurious to the infant.

The mother said that she used the shields until sometime in January 1937, always being careful thoroughly to wipe each breast with a boric acid solution before feeding the infant. In January the infant became violently ill and was removed to a hospital, where his condition was diagnosed as lead poisoning. In a subsequent suit for damages brought on behalf of the infant against the vendor of the shields, the complaint was dismissed by the supreme court, trial term, Kings County, New York.

The plaintiff argued that lead from the metallic shields was deposited in the fissures of the mother's sore breasts and that the ingestion of this lead by the infant over a period of months caused the infant's illness. The contention was that the nipple shields were not only inherently dangerous but were marketed without proper warning or instructions. The supreme court admitted that a person marketing inherently dangerous products must give fair and adequate warning or instructions to the using public. The evidence showed, however, that many thousands of these shields had been used, both in England and in the United States, for more than ninety years, but that in all that time only once had any member of the medical profession questioned the safety or efficiency of their use. That one occasion was in an article published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, May 15, 1926, in which reference was made to 2 cases. One of those cases, the court said, was hearsay and the other showed that the mother had been negligent in washing her nipples. In fact the article stated:

Lead poisoning in nursing infants is extremely rare . . . One cannot be certain that the nursing infants may not also have sucked lead from the skin or hair of the mothers, or carried it to their mouths on their hands.

. . . we have not found the use of lead nipple shields by nursing mothers previously demonstrated as a source of lead poisoning in infancy.

The article also enumerated other sources of lead poisoning in infants of nursing age as glass nursing bottles containing lead; nursing bottle stoppers, both of metallic lead and of lead-containing rubber and lead frames in which nursing bottles are held; lead powders used by mothers as cosmetics, and inhalation of lead dust, lead paint from a doll and clothing material impregnated with lead. The court added that many persons are allergic to conditions which do not affect the normal individual and that, from the evidence, there was no way of determining whether or not the infant in this case was the subject of a peculiar hypersensitivity to the almost insignificant lead deposits on the mother's breasts.

The plaintiff was required to prove, first, that the injury resulted from lead ingested, even though the mother followed the directions accompanying the shields; second, that the shields were inherently dangerous and poisonous; and, third, that the defendant was negligent in marketing such dangerous and poisonous appliances. The court stated the general principle applicable to the sale of inherently dangerous products: "There must be knowledge of a danger, not merely possible, but probable." The evidence in this case, said the court, showed that

the metallic shields had been used by many thousands of persons and over a long period of time without resultant harm. Neither the manufacturer nor the marketer had any knowledge or indication that the product was in any sense dangerous. Since the defendant knew of no dangers against which the public should have been warned, it was not negligent in putting such product on the market in the manner in which it did. A manufacturer, concluded the court, may not be charged with negligence where some unusual result occurs that cannot reasonably be foreseen and is not within the compass of reasonable probability. The court therefore held that the evidence failed to sustain the allegations of the complaint. Complaint dismissed and judgment for the defendant.—*Clary v. John M. Maris Co.*, 19 N. Y. S. (2d) 38 (N. Y., 1940).

Malpractice: Liability of Hospital for Negligent Acts of Nurse During Operation.—The patient submitted to a cystoscopy in the defendant hospital, a private noncharitable institution. When the physician was ready to perform the operation, he asked a nurse, employed by the defendant hospital and in charge of the operating room, for a 5 per cent solution of cocaine and informed her that there was a 10 per cent solution in the cabinet. The nurse prepared a solution and gave it to the defendant physician, who injected it into the patient's urethra preliminary to passing a catheter. The physician immediately detected an unexpected reaction, and an examination of the bottle from which the solution was taken disclosed that it had contained sodium hydroxide instead of cocaine. Both solutions were colorless and odorless. As a result of the injection of sodium hydroxide, the patient suffered serious burns which developed into strictures. The patient died fifteen months later from other causes, but his executor filed suit in the supreme court, Nassau County, N. Y., against both the physician and the hospital for damages allegedly caused by the injection. The jury returned a verdict in favor of the defendant physician and against the defendant hospital. The trial court, however, granted the hospital's motion to set aside the verdict and dismiss the plaintiff's complaint.

The general competence of the nurse was not questioned; nor were there any suggestions that the hospital had been negligent in either hiring her or retaining her in its employ. The defendant hospital contended, however, that it was not responsible for the negligence of its nurse in the treatment of patients. A hospital, said the court, whether charitable or private, is immune from liability for the negligence of its doctors or nurses with respect to any matter relating to the patient's medical care and attention. In *Schloendorff v. Society of New York Hospital*, 211 N. Y. 125, 105 N. E. 92, the plaintiff sought to recover damages from the defendant hospital because of an unauthorized operation performed by members of the hospital staff. The court held that, in the performance of an operation, the physician was pursuing an independent calling and was not acting as agents of the hospital. The court then added "It is true, I think, of nurses, as of physicians, that, in treating a patient, they are not acting as the servants of the hospital." In the instant case the evidence clearly showed that at the time of her negligence the nurse was assisting the physician in the operating room and attempting to follow his directions and was not acting in the discharge of administrative duties to the hospital. Relying on the *Schloendorff* case, the supreme court said that acts of preparation immediately preceding an operation are necessary to its successful performance and are really part of the operation itself. They are not different in that respect from the administration of the ether, the court continued, and whatever the nurse does in those preliminary stages is done, not as the servant of the hospital, but in the course of the treatment of the patient, as the delegate of the surgeon to whose orders she is subject. Accordingly the motion of the defendant hospital to dismiss the plaintiff's complaint was granted. This judgment was subsequently affirmed by the supreme court, appellate division, second department.—*Striwer v. The Brunswick Home, Inc., et al.*, 13 N. Y. S. (2d) 83 (N. Y., 1939); 20 N. Y. S. (2d) 430 (N. Y., 1940).

Tennessee State Medical Association, Memphis, Apr. 14-16. Dr. H. H. Shoulders, 706 Church St., Nashville, Secretary.

Texas, State Medical Association of, Houston, May 11-14. Dr. Holman Taylor, 1404 West El Paso St., Fort Worth, Secretary.

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Fourteenth Annual Meeting, Held in Chicago, Nov. 7 and 8, 1941

The President, DR. LAWRENCE D. THOMPSON,
St. Louis, in the Chair

(Continued from page 1162)

Studies in Immunity to Influenza Virus and Hemolytic Streptococcus Infections

DRS. CHARLES A. DOAN, ORAM C. WOOLPERT, CESAR MERINO, JOHN SCHWAB, MARION BEARD and S. SASLAW, Columbus, Ohio: Schwab, Blubaugh and Woolpert in preliminary experiments, employing mice, observed a shorter survival period and a higher mortality rate in animals inoculated intranasally with mixtures of *Streptococcus hemolyticus* group C (Lancefield) and influenza virus A than in those receiving either agent alone. Recently Andrews and Glover have demonstrated conclusively the aerial transmission of a combined streptococci-influenza infection in ferrets.

That more detailed analyses of the humoral and cellular reactions occurring under such conditions might be made, exploratory studies were begun some two years ago on *Macaca mulatta* monkeys. It has been found that an intranasal instillation of 10,000 mouse minimum lethal doses of influenza virus A is followed promptly by the appearance of a striking granulopenic leukopenia and that within eight to twelve days virus neutralizing antibodies may be demonstrated in the blood serum coincident with the reestablishment of the preinfection white cell equilibrium. Fever, anemia, anorexia and positive blood cultures were not observed, and no fatalities occurred in cases of this mild, uncomplicated infection.

Parallel intranasal inoculations of 750,000,000 hemolytic streptococci of group C produced in normal monkeys an immediate characteristic polymorphonuclear leukocytosis, the white cells numbering 30,000 to 50,000 per cubic millimeter, fever, anorexia, gradual weight loss and progressive hemolytic anemia with reticulocytosis. Cultures from the throat remained positive for these organisms for variable periods. The opsonocytaphagic index, precipitin and antistreptolysin titers remained unchanged. The cellular defenses, as reflected in the fluctuating granulocytosis, gradually prevailed, and coincident with the reestablishment of the preinfection equilibrium in the white cells the hemolytic streptococci disappeared from the throat and the temperature became normal. Most significant of all, the anemia, which had been progressive up to this point, was reversed, and a spontaneous return to normal of the red cell and hemoglobin values promptly followed. All normal monkeys under optimum dietary conditions survived this initial infection with hemolytic streptococci.

As might be anticipated, an occasional animal continued to harbor hemolytic streptococci in the throat. In such animals spontaneous clinical exacerbations occurred with the development of albuminuria, hematuria, edema and hypertension, with histologic evidence of renal pathologic conditions post mortem. In recovered monkeys reinoculation with the organism was accomplished three to five months after the original infection. In sharp contrast to the original reactions, no leukocytosis, and little or no fever or other constitutional manifestations of disease developed, but the opsonocytaphagic index rose sharply within twenty-four hours, suggesting a greater individual acquired polymorphonuclear efficiency in dealing with the invaders.

In other experiments the initial influenza virus infection was followed in four days and seventeen days respectively by superimposed hemolytic streptococcus infection. Usually the charac-

teristic polymorphonuclear leukocytosis was observed in monkeys which had received the virus only four days previously, and survival was the rule.

In the others, however, the leukocytosis was completely inhibited, and in 1 animal (monkey 3) death followed within thirty-two days of the original virus infection and on the fifteenth day after the superimposed streptococcus inoculation, with generalized sepsis, as proved by repeated blood cultures and cultures of all organs post mortem.

When hemolytic streptococcus infection was followed by a superimposed virus inoculation at the same two arbitrary time intervals, the virus invasion, after the four day interval, was reflected either by transitory leukopenia (lasting twenty-four hours) or by delayed granulocytopenia (lasting ten to fifteen days) and the neutralizing antibodies were demonstrable as in the uncomplicated influenzal infections. When a seventeen day interval was permitted to elapse, usually all evidence of the streptococcal infection had disappeared and the influenzal reaction occurred with characteristic leukopenia, followed by appearance of neutralizing antibodies in the time relationships already described.

When influenza virus and hemolytic streptococci were instilled simultaneously into the nasal passages of normal monkeys, immediate leukocytosis developed and subsequently leukopenia suggestive of a delayed virus effect.

The relative mildness of the clinical manifestations, associated with the distinctive humoral and cellular reactions, which reflect invasion of mucous membrane by the agents employed, make the normal healthy, well nourished monkey an ideal medium for this type of study. Preliminary investigations with various deficient diets already indicate a materially altered resistance in terms of the factors here analyzed, with a corresponding alteration of clinical morbidity and mortality.

DISCUSSION

DR. M. A. BLANKENHORN, Cincinnati: I should like to ask Dr. Doan whether he has been able by the combination of these things to cause a definite pathologic picture in the lungs. In particular, has he been able to produce the pathologic picture seen in the lungs of patients who died in the epidemic of influenza of 1918 and thereabouts?

DR. C. A. DOAN, Columbus, Ohio: There has been 1 spontaneous death in this particular series. At autopsy the monkey showed pathologic changes in the lung suggestive of those seen in human bronchopneumonia. We have been interested in following the lung fields, both clinically and roentgenographically, in the surviving monkeys, but there has been no evidence significant of gross pathologic changes in the lung. This does not mean that there might not be microscopic histologic changes; that remains to be seen. Because of the scarcity of monkeys we have not yet deliberately killed animals at various stages during the humoral and cellular reactions for tissue studies. Such observations are currently being made. The monkey seems to be more resistant to clinical influenza of type A than the human being and is much more resistant than ferrets and mice. Judging solely from the clinical manifestations, there is no evidence for invasion by the virus at all. It is only by following the peripheral blood cell and blood serologic changes from day to day that one may obtain indirect evidence of invasion. There have been negative reports heretofore, based on clinical data alone, of infection by the influenza virus in monkeys.

The Coagulase Test for Staphylococci

DR. WESLEY W. SPINK and JEAN JERNSTA, B.A., Minneapolis: Several in vitro tests for determining pathogenicity of staphylococci have been developed in the past. The simplest and most satisfactory clinical method is the coagulase test. An intensive study of seventy strains of staphylococci in the past three years reveals that the coagulase positive strains resist the bactericidal action of human blood. This correlation is remarkably constant. Our studies indicate that serious infections and invasion of the blood stream are due to coagulase positive strains with important exceptions that will be discussed. In 2 instances

invasion of the blood stream by coagulase negative Staphylococcus albus strains resulted in death because of the localization of the organisms on the heart valves and the establishment of subacute bacterial endocarditis.

Thermal Effect of Renal Extracts on Guinea Pigs

JOSEPH ZICHIS, PH.D., and DRs. MAURICE WALD, MORRIS E. THOMAS and M. HERBERT BARKER, Chicago: In the preparation and study of renal tissue extracts (Page and his co-workers) a rapid method of assay is urgently needed. When young guinea pigs weighing from 140 to 200 Gm. are inoculated intraperitoneally with 1 to 2 cc. of a clinically active renal extract severe hypothermia results. The hypothermic reaction appears in one to two hours, the greatest temperature fall, of 4 to 10 degrees Fahrenheit, being reached in four to eight hours, and return to normal occurs in twenty-four to thirty-six hours. In addition some of the animals have shown a shocklike reaction. Ten per cent die within twenty-four hours. Inactivated renal extracts, serums and other tissue extracts fail to show this characteristic hypothermic reaction.

In dogs with experimental hypertension, produced by wrapping the kidneys in silk, who present the picture of the malignant stage (blood pressure over 200 mm., detached retinas, listlessness, toxicity and inability to eat or drink), the administration of active extracts greatly improves the general condition. The appetite returns, the dogs move about their cages and the retina shows varying degrees of improvement, with and occasionally without notable falls of the blood pressure.

Patients exhibiting the signs and symptoms of so-called malignant hypertension treated with active renal extracts often show more improvement in their symptoms than fall in the blood pressure. The order of improvement is generally that the headaches disappear, there is a general feeling of well-being, the gallop rhythm of the heart subsides and the retinas clear of hemorrhages, exudate and papilledema. It should be stated that the average fall in systolic blood pressure ranges from 30 to 50 mm. of mercury and the diastolic 15 to 30 mm. Patients with benign or essential hypertension show a more decided fall in blood pressure associated with the disappearance of the headaches, vertigo, dyspnea, constipation and fatigability.

The hypothermic reaction has been correlated with the symptomatic improvement and a decrease in the blood pressure in both experimental animals and patients. Extracts which have produced a sharp drop in temperature in guinea pigs have regularly shown moderate to considerable clinical effect. Extracts which have produced no or slight response of the temperature have shown little or no therapeutic benefit. It is hoped that this or some similar simple test can be found to facilitate the purifying of the hypotensive factor in renal tissue extracts.

Effect on Cardiac Output of Renal Extracts

DRs. ROBERT D. TAYLOR and IRVINE H. PAGE, Indianapolis: Ballistocardiographic observations of the cardiac output were made on 15 hypertensive patients before and after treatment with extracts of kidneys ("angiotonin inhibitor") and on normal human subjects before and after administration of angiotonin, tyramine and methylguanidine sulfate.

When arterial pressure was reduced in hypertensive patients the cardiac output increased roughly 15 to 20 per cent. When extract was withdrawn and the arterial pressure rose the cardiac output decreased to its former level.

Hypertension induced in normal persons by tyramine and methylguanidine was accompanied by highly unpleasant symptoms, whereas that from angiotonin was not. The stroke volume was increased with tyramine, but coincident bradycardia reduced cardiac output. Methylguanidine produced slight bradycardia, reduced stroke volume and cardiac output. Angiotonin, on the other hand, produced little change in pulse rate and considerable reduction in stroke volume and cardiac output.

The results add evidence in favor of the view that the angiotonin-angiotonin inhibitor system plays a part in the genesis of human arterial hypertension.

The Use of Kidney Extract in Controlling Experimental Renal Hypertension and Essential Hypertension

DRS. FRANCIS D. MURPHY, JOHN GRILL, G. P. LANGENFELD, L. J. KURTEN and V. G. GUENTHER, Milwaukee: A kidney extract has been prepared from pork kidneys according to a method described by Page. It has been used to treat 11 patients with essential hypertension and rats with experimental renal hypertension. The results obtained were as follows: Seven of the 11 patients responded satisfactorily, 2 were resistant and 2 were symptomatically improved without a corresponding drop in blood pressure. All the patients had either premalignant or malignant forms of essential hypertension.

The unfavorable features have been the local and the general reactions. The local type, although painful, is not dangerous. There are two kinds of general reactions: the anaphylactic-like type, and the more dangerous kind that is associated with a sharp fall in blood pressure and peripheral vascular collapse.

Rats made hypertensive by Page's method were used for control of the extract before it was injected into patients.

DISCUSSION ON RENAL EXTRACTS

DR. EMMET B. BAY, Chicago: I should like to ask Dr. Taylor how the calculations on cardiac output from ballistocardiographic records are made with special reference to the underlying formula to which Starr has referred, i. e. that $f = m a$, an old-time physical equation. I can see how m in the equation could represent output if it can be separated from a , which represents acceleration. In the presence of a lowered diastolic blood pressure the emptying time of the ventricle might be decreased, and would not this as well as the increased output increase the a of acceleration? Is this taken into account in the calculations? These records probably show improvement in circulatory dynamics, whether or not one can say anything more than that.

DR. GEORGE E. WAKERLIN, Chicago: It is highly desirable to have a shorter method of assaying antipressor extracts than the present one involving the use of dogs, rabbits or rats with renal hypertension. Perhaps the method reported by Dr. Zichis and his co-workers is the one investigators are looking for. This procedure may be similar in principle to the frog method for digitalis. Digitalis assay in the frog, of course, involves the production of a toxic effect, which is essentially an exaggerated therapeutic response, by large doses of the drug. Obviously, more work is necessary before the method proposed can be finally evaluated. The finding of Drs. Taylor and Page that angiotonin decreased the cardiac output in normotensive human beings is most interesting. In view of the well known fact that the cardiac output is within normal limits in essential hypertension, how can the action of angiotonin on the cardiac output in human normotension be adduced as evidence for a pathogenic role for angiotonin in essential hypertension? Did Dr. Murphy and his co-workers control the possible nonspecific effect of the kidney extract in their experiments by treating a group of hypertensive patients with a similarly prepared extract of hog tissue other than the kidney?

DR. HENRY N. HARRIS, Detroit: I was interested in the side effects of one of the extracts mentioned by Dr. Zichis and Dr. Langenfeld, namely the local reactions, shock and death after injections in guinea pigs. Was the peritoneal fluid of the guinea pigs that died increased in amount, and if so was it a protein-like fluid or merely a watery transudate? Some years ago the late Dr. Andrews and I showed that a number of substances, among them bile and bile salts, if injected into the peritoneal cavity in large amounts would cause a local weeping of plasma-like fluid with resultant secondary shock. The shock described by Dr. Zichis might be such a local reaction or it might be caused by the general effects of the fluid after absorption.

DR. FRANCIS D. MURPHY, Milwaukee: As to the cases reported by Dr. Langenfeld, I believe it should be emphasized once more that the patients had had hypertension for a long time before we used the kidney extract; so I do not believe

we were fooled in our interpretation by the old post hoc ergo propter hoc argument. In our cases malignant hypertension failed to respond satisfactorily to treatment, while Dr. Page and his associates have reported favorable results in some of their cases of malignant hypertension. This difference may be explained by the fact that so-called malignant hypertension may occur in some patients who have had long-standing hypertension and well developed renal arteriosclerosis, while in others the malignant syndrome may be engrafted on a fairly normal kidney to begin with. It seems to me that there would be a distinct difference as far as treatment with renal extract is concerned in these two sets of cases. I do not wish to offer these cases as proof that kidney extract is a cure or that it solves the problem of therapeutics in essential hypertension. After using this extract, crude as it is, for about a year, we obtained satisfactory results in about 75 per cent of the cases. When a purer extract is produced a higher percentage of favorable responses is anticipated.

DR. LOUIS N. KATZ, Chicago: The question has been raised whether the ballistocardiograph is a suitable recorder of cardiac output. When Dr. Starr first described this method it did not appear to be sufficiently accurate, but more recent work has convinced me that it can give information of the output of the heart by the methods suggested by Dr. Starr. However, it should not be used for individual cases but rather for a statistical handling of a large series. With regard to the report by Dr. Murphy and his collaborators, I should like to point out that at present the extract of the kidney which has been employed requires large quantities of kidney. It is therefore not practical. Why cannot something be done to improve the manner of extracting so that a better yield can be obtained? Only when this is accomplished will the method have possibilities for widespread clinical use.

DR. PAUL STARR, Chicago: The authors conclude that the extract which lowers the blood pressure is one that benefits the patient. Is it necessarily true that lowering the blood pressure will lengthen the life of the patient?

DR. MORRIS THOMAS, Chicago: In our work with the kidney extract we found considerable symptomatic improvement. In most of the cases there has been a fall in the blood pressure. That is true in cases of malignant hypertension. The indications of improvement have been the disappearance of headaches, improvement in the general feeling of well-being, disappearance of gallop rhythm and clearing of the hemorrhagic exudates previously present in the eyes. There have been no remissions unless the extract was withdrawn. Recently we have been working with benign or simple hypertension, and we have noted in the patients a much greater fall in blood pressure. In 1 with severe essential hypertension the blood pressure was reduced to 145 systolic and 90 diastolic, but with withdrawal of the extract the pressure rose in a few days to 206 to 220 systolic and 120 to 140 diastolic.

DR. IRVINE H. PAGE, Indianapolis: All the kidney extracts which have been employed are crude. The question to be determined is whether there is an active depressor substance in them. With regard to Dr. Starr's question, it has long been thought on the basis of a teleologic explanation that elevation of the blood pressure is a desirable thing. Perhaps it is under certain circumstances, but on the whole the evidence points strongly the other way. We became convinced that the blood pressure could be lowered profoundly without the evidence of peripheral tissue anoxia. On the whole, clinical improvement seemed to follow reduction in blood pressure resulting from surgical operations, thiocyanate therapy or spontaneous reduction. Reduction of the arterial pressure in a hypertensive patient is desirable, not undesirable. It should be stressed especially that renal insufficiency does not occur even when the blood pressure falls sharply. The fear that it will occur appears unjustified. Measurement of the urea clearance following reduction of the blood pressure by a number of means showed beyond doubt that there was no gross over-all reduction in renal efficiency, but the interpretation of the urea clearance is complex;

hence it is necessary to resort to methods which give a more exact picture of the intrarenal hemodynamic changes. The insulin and diodrast clearances, as developed by Smith, Corcoran and Alving, will demonstrate such changes. The pathologic change which seems characteristic of the hypertension of most patients is constriction of the efferent glomerular arterioles with some reduction in total renal blood flow. The interesting fact demonstrated by Corcoran is that kidney extract causes relaxation of the efferent arterioles both in experimentally hypertensive animals and in human beings with hypertension along with a moderate increase in blood flow. As Corcoran and I have emphasized, the actual blood flow through the kidney is the result of two opposing factors: (1) the mean systemic arterial pressure working against (2) the effective resistance of the flow of blood through the kidney; thus if the resistance in the kidney is lowered at the same rate at which the mean arterial pressure is lowered there should be no increase in the renal blood flow. But such a direct proportionality is seldom seen with the administration of kidney extract, with the result that some increase occurs in blood flow along with relaxation of the efferent arterioles and fall in the systemic mean pressure. These observations suggest a certain degree of specificity in the kidney extract; I fully recognize the danger of using the term specificity. There is only scant evidence at present which suggests specificity, but, on the other hand, there is nothing against the notion that has so far been discovered which suggests that these extracts when properly prepared are not specific. The most obvious objection to the results obtained from study of the kidney is that the changes might be due to pyrogenic reactions. Pyrogens have been shown by Smith to cause an intrarenal hemodynamic change somewhat similar to that produced by kidney extract. Actually, thermal reactions have occurred in only a few patients. It seems unlikely that the changes could have been the result of pyrogenic reaction. Dr. Taylor has told you of the effect on the cardiac output. Again, this evidence might be taken to indicate the presence in kidney extract of a substance which is at least unusual in its action. The increase in the cardiac output which follows the reduction in the blood pressure is in some ways just the reverse of what one might anticipate. Perhaps one of the most dramatic effects of kidney extract is that on the eyegrounds. The reversal of the pathologic changes is often complete. Such reversal never occurs in malignant hypertension with the exception of hypertension concomitant with toxemia of pregnancy. I think one could say categorically that, whatever the nature of the kidney extract, its effect, direct or indirect, on the eyegrounds is remarkable. This emphasizes a point which I wish to make, namely that both Dr. Murphy's and our patients have for the most part had far advanced malignant hypertension. We have purposely chosen them because of the clarity with which objective evidences of the disease could be followed and because of the experimental nature of the work. We have not attempted to select patients who might give the best results, nor have we selected the extracts which give the best results. In general, it appears that when the renal function, as measured by diodrast T_m , is below 20 from the therapeutic point of view, giving kidney extract is hardly worth while. One could hardly expect to reverse the morbid process in kidneys so badly damaged, and keeping the patient alive is hardly more than a tour de force. I should like to point out that the preparation of these extracts is a question not so much of the difficult procedures involved as of the impurity of the end product and the poor yield. We are forced to work entirely empirically and up to recent months have had to depend on assay on hypertensive dogs and rats. Recently we have come to employ a test which determines the destruction of angiotonin and which we hope will facilitate assay greatly. Apparently the destruction of angiotonin and the lowering of blood pressure go hand in hand. I have had no personal experience with Dr. Zichis's test. I hope it will prove reliable because it would be an enormous time saver if it did. I do not consider the administration of kidney extract a practical treatment for hypertension at present. Whether it will become practical depends on future research, which is altogether

unpredictable. Whether it proves practical or not it will open another avenue of approach to the difficult problem of hypertension. If the extracts contain substances with therapeutic activity more will be known about them in the course of time. But let me emphasize that if these are merely interesting substances which are found by more exacting testing to have no therapeutic effect then the search for them will have been a lot of fun; it is only when one enjoys one's research that it seems worth doing.

JOSEPH ZICHIS, PH.D., Chicago: I did not ordinarily observe the evidence of fluid concentration. After the guinea pig died all the material seemed to be absorbed, and we have not encountered peritonitis at all.

DR. ROBERT D. TAYLOR, Indianapolis: Dr. Katz helped me a good deal. The formula used was devised by Dr. Starr and published by him. He checked this method with the acetylene and ethyl iodide methods and found it to be within reasonable limits of accuracy in determining cardiac output. As for the decrease in cardiac output produced by angiotonin in normal persons, one must not forget that the experiments were with acute disease and the output cannot be compared with the state seen in chronic hypertension, which, as is well known, is usually normal. In hypertensive patients there is usually cardiac hypertrophy. In our patients we noted that those who had little or no cardiac hypertrophy had a low normal or a subnormal cardiac output, while those whose hearts were hypertrophied had an output in the high normal range. It may well be that the cardiac output in hypertension is maintained at a normal level by adaptive cardiac hypertrophy. In measuring cardiac output with the ballistocardiograph we noted some interesting changes in the tracings themselves. Over the past two years Dr. Isaac Starr has correlated various heart diseases with the tracings produced by the ballistocardiograph. Among the changes he has described is the "early M" complex usually seen in hypertension. This is produced by elevation of the normal H wave and shortening of the normal HI segment. These alterations combined with normal J and K waves produce a capital M. We have noted that angiotonin produces this in normal persons whereas tyramine and methylguanidine sulfate do not, and further that hypertensive patients treated with antipressor renal extracts produce tracings that compare to normal ones. Since both the ballistocardiographic and the renal hemodynamic changes of hypertension are mimicked by the action of angiotonin and, in patients with hypertension, reversed toward the normal by administration of antipressor renal extracts, a pathogenic role of angiotonin in hypertension seems not unlikely, and the specificity of these extracts is further confirmed.

DR. G. P. LANGENFELD, Milwaukee: The only question that has not been discussed is whether other tissue has been extracted or injected as a control. We have not used any other tissue in this way. The only one used has been kidney tissue.

The Localization of Human Bundle Branch Block

DRS. W. C. BUCHBINDER and FRANK NEUWELT, Chicago: The simultaneous registration of the arterial pulse wave (brachial) by the Hamilton manometer and the electrocardiogram was secured on 37 patients having intraventricular block: with a QRS complex of 0.12 second or more. The time difference between the onset of mechanical ejection of the left ventricle and the electrical systole (QE interval) was determined for the 37 and for 20 patients without block who served as controls. The patients with intraventricular block were then separated into functional groups: (1) those having a normal QE interval and (2) those showing an interval prolonged by nearly 50 per cent. Each group shows distinctive electrocardiographic patterns. In the first, QRS₁ was chiefly down or an S wave was present; in the second, QRS₂ was up. The data presented are pertinent to localization of human bundle branch block lesions and are in accordance with the current views localizing the common type in the left bundle system and the uncommon or the one showing an S₁ in the right bundle system.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pathologic Lesions in Macula and Area Centralis. K. B. Benkwith, Montgomery.—p. 221.
Management of Third Stage of Labor. T. B. Woods, Dothan.—p. 226.
Error and Delay in Diagnosis of Hydronephrosis. E. C. Coats, Florence.—p. 230.

Thymol in Tuberculosis.—Searcy and his co-workers administered 0.3 Gm. of thymol three times a day in the treatment of advanced pulmonary tuberculosis among 6 uncooperative patients. The thymol was given after each regular meal with a glass of whole milk to facilitate absorption. After seven weeks of therapy the patients had improved to such a degree that the daily dose was reduced to 0.3 Gm. given twice a day. During treatment there was no change of environment or of the dietary regimen. After nine weeks of treatment none of the patients had experienced any ill effects from the therapy. The authors realize that their clinical material is meager and that not enough time has elapsed to permit definite conclusions, but they believe that the improvement in their 6 patients is too uniform to be a coincidence. They suggest that the beneficial effect of thymol therapy in fungous disease warrants further study of the use of thymol, thymol combinations and derivatives in the mycobacterial diseases, i. e. tuberculosis and leprosy.

Hypertension and Pyelonephritis.—Kimmel reviewed the records of 510 children aged 2 months to 15 years who had pyogenic renal disease. Pathologic processes were demonstrated in 91 by urographic examination, at necropsy or at examination of a removed kidney. The group was further studied to determine in how many elevation of the blood pressure was present. For 33 of the children with unilateral renal lesions nephrectomy was performed, for 35 with unilateral renal lesions nephrectomy was not performed and in 23 the renal lesions were bilateral. Blood pressure was considered normal if it was less than 120 mm. of mercury systolic and 80 mm. diastolic, regardless of age. Of the first group of patients the blood pressure on admission in 1 was 138 systolic and 88 diastolic and four years later was 110 systolic and 60 diastolic; in 1 before operation it was 170 to 210 systolic and 140 to 166 diastolic and seven months after nephrectomy was 104 systolic and 74 diastolic. In 1 of the second group of patients on initial examination it was, respectively, 160 and 118 and 148 and 110 three years after an apparent cure after treatment with a ketogenic diet; in 1 on admission it was 148 and 90 and 120 and 80 two days after a nephrostomy on the left side; in 1 on admission it was 172 and 140 and nine months later after several dilations of the right ureter it dropped to 134 mm. systolic; and in 1 it was 200 and 170 soon after admission, and after a bilateral resection of the splanchnic nerve it dropped to 180 and 130. In 1 patient of the third group the blood pressure was 126 and 94 on admission, and five years later, after resection of the presacral nerve and resistance to methenamine and ammonium chloride, it was 142 and 98; in 1 on admission it was 142 and 104, and five years after a suprapubic cystostomy and a sphincterotomy it was 106 and 72; in 1 on admission it was 230 and 170, and after the patient had been five days in bed it was 160 and 120. The last patient died more than a year after dismissal. The age on admission of the 8 patients with hypertension varied from 7 to 14 years. In 3 of the 8, one atrophic kidney was present. In only 2 of the 8 was the level of urea in the blood elevated. Arteriosclerosis was present in seventeen of the thirty-three pyelonephritic kidneys removed at operation. The view that renal ischemia may elevate the blood pressure in human beings seems to be suggested. Hypertension associated with chronic pyelonephritis in children apparently is not rare.

Myocarditis Following Chemotherapy.—French and Weller state that, during the last four years, interstitial myocarditis with eosinophilic cellular infiltration was occasionally encountered at necropsy at the University Hospital Study revealed that medication during the terminal illness with one or more of the sulfonamide drugs was the only common factor. Survey of the necropsy material (1,706 patients) for 1937 to 1941 revealed that 283 patients had been given one or more of the drugs during the last few weeks of life. In 126 of these patients significant interstitial myocarditis was present. The age of the patients varied from 1 month to 87 years. The amount of the drug (administered over a few hours to several months before death) which apparently produced significant infiltration varied from 5 Gm to more than 200 Gm. Interstitial myocarditis was not present in any patient who had not received chemotherapy for at least thirty days prior to death. No macroscopic changes attributable to the sulfonamide therapy were observed in the affected hearts. The microscopic features of the lesion included interstitial myocarditis, usually with a paravascular and sometimes also with a diffuse distribution of the cellular infiltrations. Both ventricles and auricles were widely involved. The looser auricular myocardium often exhibited a heavier paravascular infiltration than did the compact ventricular muscle. Some foci were likewise seen in the epicardium. The cellular infiltrations contained large mononuclear cells of clasmotocytic type and numerous cells with granular eosinophilic cytoplasm. Except for the acidophilic cytoplasm, some of the eosinophils resembled plasma cells. Eosinophilic infiltrations were occasionally observed in the liver, lungs and kidneys. In some instances the bone marrow, spleen and lymph nodes showed a relative increase in eosinophils. Similar eosinophilic interstitial myocarditis was produced in mice and rats receiving daily intraperitoneal injections of the sulfonamide drugs. The eosinophilic character of the infiltrations makes idiosyncrasy to the drugs seem likely. The lesions were not irreversible. Nevertheless, it is impossible to evaluate the effect that such a lesion might have on the heart of a person seriously ill from some other pathologic condition. Therefore, during therapy the efficiency of the cardiovascular system should be determined at frequent intervals. The authors stress the need of keeping patients who are receiving these drugs under the closest clinical scrutiny and warn that the amount and the duration of therapy should not exceed the amount and duration consistent with beneficial results.

Bronchiogenic Carcinoma and Pulmonary Asbestosis.—Holleb and Angrist report 2 cases of bronchiogenic carcinoma associated with pulmonary asbestosis. An attempt to demonstrate unusual amounts of silica in the lungs was unsuccessful. 240 mg was present in the lungs of the first patient and 45 mg in those of the second per hundred cubic centimeters of tissue. The silica content in the first patient was only slightly elevated, while that in the other one definitely fell within known nonpathologic limits. Therefore the diagnosis of pulmonary asbestosis must rest on (1) a history of prolonged exposure to the dust (twenty-five years for each patient), (2) the presence of a productive cough in 1 and of cough and severe exertional dyspnea without cardiac disease in the other and (3) evidence of asbestosis: diffuse interstitial pulmonary fibrosis, asbestosis bodies, macrophages and giant cells. Inhaled asbestos fiber undergoes dissolution and phagocytosis and may eventually disappear, but it leaves behind irreparable damage. As both patients were employed for a long time in an occupation in which the exposure to asbestos dust was relatively low it is conceivable that extensive damage could result as a summation effect without an appreciable accumulation of asbestos in the lung.

- Senile and Arteriosclerotic Psychoses.**—Rothschild differentiates the two psychoses, seen in 60 cases, as follows. Senile psychosis tended to occur at a later age and was apt to last longer than arteriosclerotic psychosis. The course of the former was gradually progressive and of the latter sudden, and the illness was sometimes brief and stormy. Intellectual impairment was generally more pronounced in senile condition. Depressive and hypochondriac symptoms were often observed in arteriosclerotic disease but seldom in senile disorders. Paranoid forms of senile psychosis resembled arteriosclerotic psychosis in that the intellectual functions were usually well preserved, but outspoken and chronic paranoid syndromes were not encountered in arteriosclerotic disease. Headache, dizziness and apoplectic form phenomena were observed in arteriosclerotic patients. Other characteristics were syncope, convulsions, explosive emotional outbursts and clinical indications of cardiac disturbance. Peripheral (radial) sclerosis and hypertension were observed with equal frequency in the two psychoses. Anatomically pure forms of each psychosis occurred less often than mixtures of the two processes, but clinically a mixed psychosis was not nearly as frequent. A diagnosis of senile or arteriosclerotic disease, especially of the latter, is made too often. A toxic or a symptomatic psychosis is a common source of error.
- Alcoholic Encephalopathy.**—Jolliffe and Wortis evaluate results of nutritional and vitamin studies in delirium tremens, the Korsakoff psychosis, Wernicke's syndrome and the various cerebral disorders due to deficiency of nicotinic acid. Dietary insufficiency as observed in chronic alcoholism is stressed. The effect of alcohol by itself has still to be evaluated. Vitamin therapy, to be effective, must be instituted before irreversible

Culture Studies in Chronic Gonorrhea.—Maloney and his collaborators examined cervical secretions of 2,429 women of the prostitute class, of 73 untreated women with clinical evidence of gonorrhea and initially positive cultures and the pooled cervical and/or urethral secretions of 56 women to determine the efficacy of the cultural method for isolating the gonococcus. Most of the 2,429 women had varying degrees of cervicitis which might commonly be considered the result of gonococcal infection. A single culture of the cervical secretion revealed positive results in approximately 21 per cent. For each of the 73 patients at least ten and usually twenty culture plates were

used prior to the patient's release from custody. The cultures of 46 per cent remained positive throughout the study of three or four months; the cultures of the cervical secretion of 42 per cent remained positive for one or more observations and then abruptly or sometimes gradually they became negative and remained so during the remainder of the observation period; 12 per cent had characteristically positive cultures followed by numerous consecutive negative cultures and subsequently by one or more positive cultures occurring sporadically during the observation period. The pooled material of all the 56 patients showed the gonococcus, the cervical secretions of 53 and the urethral secretions of 23. A second cultural study was carried out on the secretions of 604 patients. A comparison of the results indicates that approximately one sixth of the patients whose original cultures were negative had positive cultures when the secretions were reexamined. Originally positive cultures were confirmed by reculture for only three fourths of the patients. The authors conclude that it may be unwise to withhold treatment from women solely on the basis of a negative culture when clinical and epidemiologic evidence of infection exists.

Bismuth Stomatitis and Albuminuria.—Peters states that the true incidence of the association of bismuth nephrosis or albuminuria with severe ulcerative stomatitis cannot be determined from the 6 cases recorded in the files of the Johns Hopkins Hospital. This is due partly to the failure in these cases to classify routinely the mild reactions to bismuth therapy and partly to the fact that when one complication was observed no attention may have been paid to the presence or the absence of the other one. In addition to the 6 patients who were hospitalized because of the severity of their complication, there were 7 with a similar but mild complication who were treated as outpatients. The work of Corson, Decker and Williams indicates that bismuth is mobilized by the administration of ammonium chloride. Peters suggests that it is probable that acidosis from any cause will lead to a mobilization of bismuth from the skeletal, muscular and visceral depots. That this may be possible is indicated by the test performed on 5 of the 6 patients who showed a lowered carbon dioxide combining power during the stomatitis and nephrosis. Bismuth should be administered cautiously to patients susceptible to acidosis, for example to patients with diabetes, previous renal damage, intercurrent infections, impaired food intake or retention and heart disease when ammonium chloride is given for its diuretic action. The acidosis which may result may cause bismuth to be mobilized to the extent of producing toxic phenomena.

Chemotherapy and Serotherapy for Otitis Media.

According to Ganz and his associates, the early treatment of acute otitis media with myringotomy and sulfonamide derivatives supplemented with immune serum for patients who were

not clinically convalescent within forty-eight hours prevented "surgical" mastoiditis in 40 patients with hemolytic streptococcus or pneumococcal infections. Experience for more than one year in more patients is necessary for a critical evaluation of the method, but the regimen appears most promising. Chemotherapy was continued, often in reduced doses, for three weeks for all patients.

Goiter and Myasthenia Gravis.—According to Kowallis and his collaborators, subtotal thyroidectomy alleviated the symptoms of 1 of 4 patients with hyperthyroidism and myasthenia gravis of the bulbar type. When the two diseases coexist, either may easily be overlooked. The response to prostigmine of the patient with myasthenia gravis is an important diagnostic aid. Iodine may be administered as an aid in the diagnosis of exophthalmic goiter; however, in their patients its effect was not consistent. Its characteristic effect on exophthalmic goiter might not be obtained when untreated myasthenia gravis coexists. The basal metabolic rate, which is not elevated in the patient with uncomplicated myasthenia gravis, may be informative. Pathologically, both exophthalmic goiter and myasthenia gravis are associated with significant involvement of the thymus. The most favored theory of the origin of muscular weakness in myasthenia gravis suggests faulty transmission of nerve impulses due to a defect at the myoneural junction. When exophthalmic goiter and myasthenia gravis coexist, the goiter may precipitate the myasthenia in a patient with a latent tendency toward its development. Another, but less likely, possibility is that exophthalmic goiter may rarely produce muscular disturbances identical with those of myasthenia gravis. The prognosis for patients with the two diseases is grave, particularly if the myasthenia is of the bulbar type. Thyroidectomy for exophthalmic goiter complicated by myasthenia gravis offers certain difficulties. The patient must be able to dispose of tracheal mucus. In the instance reported by the authors, preoperative treatment with prostigmine resulted in sufficient improvement in muscular strength for them to feel no concern in this regard.

Sodium Sulfadiazine for Pneumococcal Pneumonia.—Donm and his associates gave 25 consecutive patients with pneumococcal pneumonia sodium sulfadiazine intravenously. Of the 25, 4 who represented extremely poor therapeutic risks died. There was no significant difference between the mortality with a dose of 2 Gm. given every twelve hours and that with 3 Gm. The results were comparable to those obtained by oral therapy with sulfadiazine. The administration of sodium sulfadiazine intravenously is to be used not as a routine but only when oral therapy is impracticable or impossible.

Serum Protein in Cirrhosis of Liver.—Post and Patek determined the albumin-globulin ratio of 61 and the nitrogen balance of 5 hospitalized patients with cirrhosis of the liver. Of the 61 patients, 54 had an abnormal albumin globulin ratio on admission. The prognosis as to duration of life became increasingly grave as the level of serum albumin decreased. The level of the serum globulin and the value for total proteins in the serum had no such bearing. Clinical improvement was associated with a rise in the serum albumin level toward normal. In patients who failed to improve there was no sustained rise. The level of serum albumin was significantly lower in patients with ascites than in those without ascites. Diuresis was associated with a rise in serum albumin. The mean value for serum albumin at which diuresis occurred was 3.1 Gm per hundred cubic centimeters. The nitrogen balance studies of the 5 patients revealed that although the patients remained in positive nitrogen balance during periods of high protein feeding there was no correlated rise in the level of the serum albumin. The data indicate that patients with cirrhosis of the liver absorb and retain food protein and that the mechanism for the synthesis of serum albumin is impaired.

Survival After Perforation of Infarcted Septum.—Moolten reports a case of survival for sixteen weeks after perforation of an infarcted interventricular septum in coronary arterial disease. During the twelve weeks after admission to the hospital (four weeks after the perforation) evidence of failure of the right side of the heart increased, despite treatment with digitalis and mercurial diuretics. From this case and a review of the histories of 3 similar ones the author concludes that the interventricular septum as a functional entity is of particular significance as a component of deep muscle tracts common to the two ventricles and as an agency for protecting the right ventricle by preserving the differential in pressure between the two ventricles.

Antepartum Nutrition.—According to Ebbs and his associates, the infant mortality in Toronto has been reduced about 40 per cent in twelve years since indigent mothers have had their usual diet supplemented with milk, eggs, oranges, cheese, tomatoes, a wheat germ preparation and viosterol during their pregnancy. The number of premature deliveries, miscarriages and stillbirths has been reduced and the general health of the newborn infants during the first six months of life has been singularly improved. The principles of nutrition are never more important than during pregnancy.

Surgical Kidney as Etiologic Factor in Hypertension.—From a review of the cases of hypertension observed at the Mayo Clinic Brarisch concludes that a unilateral non-nephritic, or "surgical," lesion of the kidney is not a frequent cause of hypertension and that the incidence of such lesions among patients with hypertension who are amenable to operation is

less than 1 per cent. The removal of the unilateral renal lesion will often relieve hypertension. A urogram indicating deformity in the urinary tract does not necessarily mean that the renal lesion is an etiologic factor of the hypertension. Further urologic examination is necessary for an exact interpretation. There is no specific renal lesion in hypertension. The essential factor is apparently an intrarenal vascular imbalance which permits the secretion of pressor substances. The renal lesion in hypertension most often amenable to surgical treatment is chronically unilateral, diffuse, atrophic or postoperative pyelonephritis. The deciding factor in the presence of secondary infection is not the degree of infection but the consequent lesions in the renal parenchyma which cause intrarenal secretion of pressor substances. Hypertension was observed less frequently with renal tuberculosis than as an accompaniment of other forms of surgical kidney. Bilateral renal involvement was not an etiologic factor in hypertension. A follow-up study of 198 patients who were operated on revealed that the blood pressure of 65 became and remained normal for a year or more.

Intracranial Use of Sulfadiazine.—Hurteau observed in 9 cats that the local application to a cerebral wound of several drugs of the sulfonamide group resulted in different rates of absorption. The rate was determined by extraction and chemical analysis. Sulfanilamide was absorbed most rapidly, sulfathiazole second and sulfadiazine third, and sulfapyridine was absorbed the least rapidly. Sulfadiazine when in contact with meninges or cerebral parenchyma caused no neuronal destruction and no glial reaction and only a negligible foreign body reaction in the meninges. Sulfadiazine exercised no untoward effect on the final result of wound healing.

Acro-dynia.—Gareau reports 75 cases of acro-dynia encountered in nine years: 17 from cities, 17 from smaller centers and 41 from farms, 30 were in males and 45 in females. The incidence was highest from December to June. The average age at onset was a little more than 11 months. There was a family history of acro-dynia in four families, one family having had 3 children with the disease and three families having had 2 each. Two families lost a child each from complications. Most parents dated the onset of illness to some antecedent illness. The most frequent complaints were fretfulness, irritability and unhappiness, loss of ability to sit, stand and walk, sore eyes, loss of weight, sleeplessness and rash, while the least frequent complaints were profuse sweating, loss of teeth and fever. Four patients died (1 from bronchopneumonia and endocarditis and 3 from bronchopneumonia), 71 recovered, and of these 3 were not seen after the first examination. Of the remaining 68, 57 had their tonsils and adenoids removed. For the 11 not operated on the average duration of illness was about seven months. Of the 57 operated on 30 recovered rapidly, the average duration of illness being less than three and a half months. The 4 patients who died did so before the advent of modern chemotherapy. Etiologic factors that have been suggested as causes of acro-dynia are a lesion in the diencephalon or mesencephalon similar to encephalitis, vitamin deficiency, smut infected cereals, hypervitaminosis D from sunlight, arsenical poisoning, allergy and infection. The average duration of acro-dynia is about six months. It is suggested that acro-dynia is due to a toxemia caused by infected tonsils and adenoids.

Use of Normal Human Plasma.—Newhouser and Lozner state that an enrolment of two hundred thousand donors by the American Red Cross has been raised since the United States declared war on the Axis. The medical profession can aid in the collection of a vast amount of plasma by informing patients who can give blood to do so and by allaying their apprehension of venesection. Unless vasoconstriction, hemoconcentration, venous stasis, decreased blood flow, anoxia of tissue and increased capillary permeability following injuries are promptly interrupted the changes in the tissues will be irreversible and the termination fatal. The prompt administration of an adequate amount of normal human plasma not only will halt but will reverse this sequence of events. Death from hemorrhage is due not to the loss of erythrocytes but to the decrease in the circulating blood volume. Plasma is superior to whole blood, since it promptly corrects the increased viscosity of the blood and restores the circulating blood volume. Plasma, preserved in the liquid, frozen or dried state, has the advantage over blood that it can be administered safely without typing of the donor or of the recipient and without preliminary cross matching. Liquid plasma is safe and is most economical if prepared by a closed aseptic and pyrogen free method and if used before the lapse of nine months of storage at 10 to 20 C. After it has been stored eight to nine months a progressive loss of prothrombin, complement and possibly other labile constituents occurs. Liquid plasma is satisfactory for use in hospitals, but it is not well adapted for use aboard ship, in the field of combat or in bases beyond continental limits, where longer periods of storage may be necessary. For use in the foregoing situations frozen plasma (kept at -15 to -20 C.) is ideal, as all the labile constituents are preserved indefinitely, but it must be thawed to or near body temperature, and this may not always be convenient. The restoration of properly dried plasma to the liquid state takes less than three minutes. The time consuming, complicated and expensive method necessary to prepare dried plasma is offset by the facts that it is stable indefinitely, that it survives extreme changes in temperature and that when properly packaged it is ideal for use in the field and aboard ship. For this reason the armed services have decided to use the dried form. The standard army and navy package contains a bottle of dried plasma (made from 300 cc. of citrated plasma), a bottle (300 cc.) of sterile pyrogen free distilled water and the apparatus necessary for restoration and administration. After the torpedoing of the U. S. S. *Kearny*, dried plasma was flown to and dropped by parachute to the medical officer on board ship.

Tumors in Region of Pulmonary Apex.—Stein reviews 15 cases of so-called tumor of the superior pulmonary sulcus which he reported in 1937 and 1938 and presents 12 new cases. Only 1 of the 15 patients was a Negro, and all were men. The right lung of 10 and the left of 5 was involved. The duration of life from the onset of symptoms was thirteen and four-tenths months. The first symptom was pain in the shoulder and arm on the affected side. Horner's syndrome was present in 13 and costal or vertebral changes in 11. Nine patients were irradiated with no appreciable effect; in 2 an attempt was made to remove the tumor, but because the mediastinum and the brachial plexus were involved this was not possible. Eleven of the twelve new tumors occurred in white men and one in a Negro. The average age on admission was 50.7 years. The right lung of 7 patients and the left lung of 5 was involved. The first symptom in 11 was pain in the shoulder on the affected side; Horner's syndrome was present in 8 and costal or vertebral changes in the apical region in 7. Ten patients were irradiated with no appreciable relief, in 1 irradiation and the injection of alcohol into the involved sympathetic nerves gave some relief and 1 obtained relief from symptomatic therapy only. All the patients have died; the average length of life from the onset of symptoms was twelve and three-tenths months. Although Pancoast in 1932 expressed the belief that he had described a new pathologic and clinical entity, recent evidence shows that any tumor in the pulmonary apex may produce the syndrome that he described. The evidence on which he based his conclusions is inadequate, especially since gross or postmortem evidence was not available, a bronchial origin has not been demonstrated and no anatomic structure has been designated as the superior pulmonary sulcus. Microscopic and postmortem evidence is presented which shows that the majority of the malignant tumors in the thoracic inlet or pulmonary apex are carcinomas of the terminal bronchioles of the lung.

Five Day Treatment of Syphilis.—Rattner reports 170 cases of early syphilis in which the so-called five day therapy was employed. The daily dose amounted to 0.24 Gm. of mapharsen dissolved in 2,000 cc. of a 5 per cent solution of dextrose in triple distilled water. There were 103 men and 67 women; 52 had primary syphilis and 118 presented secondary manifestations. Final clinical evaluation cannot yet be made, because experience is much too recent. Spirochetes disappeared from the lesions usually in one or two days, and all open lesions healed during the seven days of hospitalization.

The spinal fluid of 162 patients was examined and was found normal in each instance. Eighty patients have been observed for five or more months after the completion of treatment. All relapses occurred in the fourth month. Of the first 80 patients 14 had to be dropped from the study, in 28 the blood serologic reactions reverted from positive to negative (usually in the tenth week), in 2 the Kahn reaction is still positive six months after treatment but the Kahn quantitative units are steadily decreasing, in 6 (treated before the serologic reaction of the blood became positive) the reaction is still negative after eight months and in 18 a progressive improvement was demonstrated by Kahn quantitative tests; 3 of the remaining patients have relapsed, 1 has probably relapsed or become reinfectd, 2 have had reinfection and in 6 the results were "unsatisfactory when the patient was last seen" (the blood quantitative titers were vacillating rather than decreasing).

Paravertebral Injection of Alcohol for Cardiac Pain.—Perlow states that 16 of 22 patients with cardiac pain obtained complete or partial relief from pain after a paravertebral injection of alcohol. The method is simple and relatively safe and can be repeated if necessary. The objection that the injection removes the danger signal (pain) of coronary insufficiency is theoretical. The patient soon learns to heed other signals and does not harm himself. The relief of pain not only is symptomatically desirable but actually reduces the work of the heart, as the patient can rest and relax.

Sublingual Administration of Alpha Estradiol.—Hall compared the absorption ratio of alpha estradiol in a solution of propylene glycol-alcohol administered sublingually to that of alpha estradiol benzoate given intramuscularly to 98 women with menopausal symptoms. In 41 patients the variation in vaginal cornification after sublingual therapy was determined over fourteen days. At the end of this time, castrates who had received no previous therapy showed improved vaginal cornification, 15 women in the menopause showed a slight reduction of cornification, 8 had smears showing an improved estrogenic level, 5 who had had a hysterectomy had a slight reduction and 3 were definitely improved. Twenty-four of 41 patients did not maintain the same estrogenic level, 3 maintained the original high level and 14 showed much improvement. The patients who did not maintain the required level of estrogen were given an intramuscular injection of 10,000 rat units of estradiol benzoate followed by a dose of 0.1 cc. of the estradiol solution, given sublingually, five times a day (instead of the usual four) with completely adequate results. Therefore, individualization of the dose is required for effective clinical results with sublingual administration. The data justify the belief that the giving of alpha estradiol in a propylene glycol-alcohol solution sublingually produces the same effects on vaginal cornification as the giving of estradiol benzoate parenterally. Propylene glycol-alcohol solution appeared as effective, milligram for milligram, as did alpha estradiol benzoate given hypodermically.

Sexual Infantilism of Hypothyroid Origin.—Lissner reports a case in which the manifestations suggested adolescent hypothyroidism without typical myxedema. An unmarried woman of 27, who appeared twelve to fifteen years younger and whose secondary sexual characteristics were undeveloped, had had irregular, scanty menstrual periods since the age of 16. She was somewhat below normal height, her bone age was estimated at 14 years, her features were slightly puffed and she had a pulse rate of 58 to 66, a basal metabolic rate of -27, severe anemia, preference for warm weather and easy fatigability. The patient was treated for one year with thyroid. This elevated the basal metabolic rate to normal, diminished the anemia and caused the breasts to develop, the menstrual periods to become regular and the personality to become vivacious. She has married and has experienced intense libido and gratification. The pubic hair remained sparse, and no axillary hair appeared. Diethylstilbestrol (1 mg. daily, given orally) was used later, and this seemed to stimulate the growth of the pubic hair.

Carotenemia in Myxedema.—Escamilla cites 7 consecutive cases of untreated myxedema in which carotenemia coexisted. He suggests that this may be part of the typical clinical picture and may explain the yellowish color of the skin seen so frequently. The carotenemia cleared gradually under treatment with thyroid substance. Carotenemia was observed also in a patient with Simmonds' disease. It is suggested that carotenemia frequently accompanies a low basal metabolic rate. The probable explanation is that the conversion of carotene to vitamin A in the liver is hindered by the depressing effect of the lowered metabolism.

Circulation to Lower Extremities.—Dauber and his associates studied the changes in cardiac acceleration and arterial and venous pressure that occurred during the release of a tourniquet applied to the extremities and during occlusion in 27 normal young adults and in 4 subjects with moderately advanced thromboangiitis obliterans. The observations were made while the subjects were recumbent, after a rest period of fifteen to thirty minutes in a warm quiet and darkened room. Cardiac acceleration followed release of occluding cuffs in the

normal subjects but was absent or reduced in the patients with thromboangiitis obliterans. A fall of the blood pressure in the brachial artery preceded the cardiac acceleration. The fall in blood pressure was caused by the opening of a temporary low resistance pathway for blood through vessels dilated as a result of the previous occlusion. The primary mechanism inducing the cardiac acceleration is a reflex response to the drop in pressure in the central arteries (Marey's law). The cardiac acceleration is not caused by a metabolite accumulating in the constricted extremities. The assumption that the reflex arises from the occluded vessel or from the tissue of the extremity is not satisfactory.

Porphyria in Lead Poisoning—Kark and Meiklejohn attempted to trace the path of the destruction of hemoglobin in 2 cases of lead poisoning by observing the effect of intravenously injected hemoglobin on the production of bilirubin and on the excretion of coproporphyrin and urobilinogen in the urine and feces. The introduction of free hemoglobin was followed by a rapid rise in plasma bilirubin. This resembled the bilirubinemia observed by Gilligan, Altschule and Katerby in normal subjects under the same conditions. It was accompanied by a transient increase in the excretion of urinary urobilinogen. The injection caused no detectable increase in the urinary or fecal excretion of coproporphyrin. An interruption in the path by which hemoglobin is destroyed in the body was not demonstrated. Therefore the porphyria occurring in lead poisoning cannot be explained on this basis. The results lend support to the view that the anemia in lead poisoning is dyshemopoietic rather than hemolytic.

Urinalysis, Addis Count, Blood Sedimentation Rate—

Rubin and his associates followed the course of an attack of acute glomerulonephritis in 40 patients hospitalized within five days of its onset by means of determination of the blood sedimentation rate and the Addis count and routine urinalysis. The data show that while routine urinalysis usually gave normal results on the thirty-seventh day the Addis count required a close correlation between the number of days required for the twelve hour erythrocyte excretion (Addis count) to drop to the 10 million level (seventy-six days) and the time necessary for the rapid sedimentation rate to become normal (seventy-six days). The data demonstrate the inadequacy of routine urinalysis as a guide to the cessation of active disease. The simplicity of the determination of the blood sedimentation rate makes the test a valuable index of the course of acute glomerulonephritis.

New Concepts of Gonococcal Vaginitis—During the last three years Cohn and his colleagues examined 1,715 persons who had symptoms of gonococcal vaginitis or were contacts of persons with the disease. The cultures and smears of 381 were positive. The culture method was the best for

diagnosis and the pronouncement of cure of gonococcal vaginitis. Sulfathiazole therapy was the treatment of choice. Patients with vaginitis who require hospitalization may be cared for in general wards when the usual isolation technic applied for other slightly communicable diseases is employed. Treated patients may return to schools and institutions when clinical signs have cleared up and the cultures are negative. Cure may be pronounced satisfactory when culture gives a negative result every month for six months. Vaginitis will not spread from one girl to another when the vaginal discharge of an infected child is prevented from reaching the vulva of a non-infected one. Attention should be directed toward contaminated linen, diapers, rectal thermometers, enema tips and the fingers of the parent or attendant. The last mentioned item is probably most frequently the fomes in the transmission of the disease. Toilet seats are not an important factor.

Truncus Arteriosus Communis Persists.—Lev and Saphir observed a girl baby aged 18 days whose heart was the seat of a transposition with truncus arteriosus communis persists. The anatomic features of the case were as follows: 1. Only one large vessel, arising from the right ventricle, emanated from the heart. This trunk gave off the coronary arteries, the systemic vessels and two pulmonary arteries. 2. The mouth of this vessel was guarded by three semilunar cusps. 3. The right and left coronary ostia lay, respectively, in the sinus of Valsalva of the left anterior cusp adjacent to the right anterior cusp and above the commissure between the posterior and right anterior cusps. 4. There was an archlike ridge over the combined mouths of the pulmonary arteries. 5. No vessel emerged from the left ventricle. 6. There was a defect of the ventricular septum. 7. The right auriculoventricular valve had only two leaflets. 8. The foramen ovale was patent. 9. The anatomy of the muscle bundles of the right ventricle was abnormal. The authors present a phylogenetic and embryologic explanation of the anomaly.

Tuberculosis Among High School Students.—Nevius states that the patch testing of 2,562 high school students disclosed 396, or 15 per cent, who reacted positively. Roentgenograms of the 396 students showed that 66 had the primary complex and 6 the reinfection type of the disease. The cost of the testing and of making the necessary roentgenograms was \$634.87, or 25 cents per student.

Toxicologic and Pharmacologic Properties of Certain Antiseptics.—Robinson and Molitor present data on the acute and cumulative toxicity and pharmacologic properties of gramicidin, tyrocidine and tyrothricin as observed in 1,200 Swiss mice and 210 albino rats after oral, intravenous and intraperitoneal administration. Gramicidin and tyrothricin were more toxic than tyrocidine when injected intravenously and intraperitoneally. The preparations were not toxic on single or repeated administration by mouth. The physical properties of gramicidin and tyrocidine limit their application to infections in which local therapy can be employed; the absence of irritating properties in these agents gives them a definite advantage over other antiseptics and may extend the scope of their application. Although the toxicity of gramicidin and tyrothricin

is greater than that of most agents of the sulfonamide group, their extraordinary bacteriostatic activity affords a large margin of safety. Pharmacologically and toxicologically the compounds have no pronounced specific properties. They do not have a definite specific effect on the respiratory or circulatory systems. Large single doses are usually tolerated without any definite effect, while multiple small doses cause a fall of blood pressure and impair respiration. With lethal doses the respiration stops shortly before the heart does. When these compounds are used clinically, care must be taken if rapid and direct absorption into the blood stream is likely.

Esophageal Hernia.—Jones reviews symptoms presented by 91 patients with small and 37 with large hiatus hernia. The average age of the patients was 55, and most were overweight. A diagnosis was made of heart disease in 13 and of disease of the biliary tract in 22. Substernal pain was experienced by more than one third of the patients with a small but by only 5 of those with a large hernia. Pain in the shoulder, usually on the left, was noticed by about one fourth of all the patients. The pain of 8 of the patients with a small and of 4 with a large hernia radiated to the arm, and pain in the hand and fingers was complained of by 5 of the 8. Palpitation was noted by 6 patients with a small and by 4 with a large hernia. Dyspnea was noticed, respectively, by one tenth and by one third of the patients. Epigastric pain occurred in two thirds of 78 hospital patients and in 19 of 45 private patients. Pain in the costal margin on the right and/or the left side was present in 21 of the 91 patients and in 11 of the 37. About one fourth of the patients complained of pain in the back, and 4 patients with small hernias experienced pain directly under the left or the right scapula. Two of the latter had disease of the gallbladder. Axillary pain was noticed by 3 patients with a small hernia and difficulty in swallowing by 4. Heartburn was a characteristic symptom of small hernia in 14 private patients but in only 2 ward patients. Pain in the right side of the chest, shoulder or arm was observed by 13 patients with a small and by 6 with a large hernia. Eight of 25 patients with substernal pain, 4 of those with pain radiating to the shoulder and 3 of those with pain radiating to the arm stated that exertion frequently initiated the symptom. Nervous tension and acute emotional disturbances initiated symptoms suggesting angina pectoris. The intake of food was responsible for initiating substernal pain in 15 of 25 patients and in half of the patients complaining of pain radiating to the shoulder, arm or fingers. Only 11 patients had heart disease that may have contributed to the presenting symptoms. Study suggests that the pain in hiatus hernia is probably mediated over visceral afferent fibers supplying the esophagus and the cardiac or fundic portion of the stomach, or over the sensory afferent fibers from the diaphragm contained in the phrenic or middle or lower thoracic nerves. Overdistention of the esophagus or the herniated portion of the stomach may thus be responsible for anginal pain in any or all of its components. Treatment is essentially medical. Phrenicectomy or surgical repair is justified only for large hernias or when

medical measures fail. Acute symptoms are frequently helped by administration of glyceryl trinitrate. Assuming an upright or a semiupright position after eating is desirable. Adequate physical and emotional rest, sedation when needed and the avoidance of exercise shortly after the intake of food are valuable measures. Accompanying coronary disease and cholelithiasis should be properly evaluated.

Experimental Pulmonary Embolism.—Megibow and his colleagues measured directly, after the experimental production of pulmonary embolisms in 14 normal anesthetized or unanesthetized dogs, the pulmonary and the systemic arterial pressure, the systemic venous pressure and the heart and respiratory rates. Major multiple minor pulmonary embolisms were followed by systolic and diastolic pulmonary hypertension. Changes in the systemic arterial pressure were not striking. The systemic venous pressure usually rose; it rarely fell or showed no change. Changes in heart rate were inconstant. Ventricular fibrillation occasionally appeared terminally in an animal. Rapid progressive respiration usually developed at the same time as or soon after pulmonary hypertension ensued. Most frequently progressive cyanosis accompanied the respiratory changes. The theory of reflex coronary vasoconstriction as a cause of "sudden death" is hardly supported by the experiments, since mechanical factors explain the possible changes in coronary circulation. Death in cases of pulmonary embolism appears to be due to a rapid or slow failure of the right side of the heart, as a result of obstruction to the pulmonary vessel. So-called hypokinetic circulatory failure is in reality rapid failure of the right side of the heart.

Fusospirochetal Onychia and Paronychia.—Benedek believes that his case of onychia and paronychia caused and sustained by fusospirochetal organisms for two years is the first to appear in American literature. The progress of the condition,

without lymphangitis or lymphadenitis, was slow but definite. The local and intravenous administration of neocarsphenamine failed to produce a cure, but the surgical removal of the affected nails resulted in prompt healing.

Malignant Meningiomas.—Turner and his associates state that among 370 intracranial meningeal tumors examined microscopically 36 showed definite malignant characteristics; 22 occurred in men and 14 in women. Twenty-two occurred during the third, fourth and fifth decades and the others among the ages of 8 and 60. The forms of the tumors were frequently bizarre and atypical. This, the authors suggest, is to be considered as progress of the anaplastic process beyond the stage of simple sarcomatous or malignant properties. The giant cells, seen frequently in the 14 more malignant tumors (11 occurred in male patients) were considered by Globus as evidence of vigorous cell growth. He believed that these cells establish a link between quiescent and malignant meningiomas. In many of the 22 low grade tumors or those with early malignant changes early or incomplete forms of giant cells were observed.

Thromboangiitis Obliterans.—Theis and Freeland report observations on studies of the arterial blood oxygen. Deficient oxygenation of the arterial blood was usually present in patients with thromboangiitis obliterans during the active stage of the disease. After two to six weeks of treatment the increase in the oxygenation of the arterial blood was accompanied by clinical improvement and in some cases by recovery (five years). The deficient oxygenation in most of the patients was affected by smoking. Prior to 1937 only sodium thiosulfate was available, but since then sodium tetrathionate (which is slower in action but more prolonged in its effect) has been used. For acutely affected persons, when an immediate effect was desirable injections of the thiosulfate were given every other day and the tetrathionate on the alternate days. As the acute stage subsided, biweekly or weekly injections of the sodium tetrathionate solution were given. The usual intravenous dose was 1 Gm. of sodium thiosulfate and 0.4 or 0.6 Gm. of sodium tetrathionate dissolved in 10 cc. of sterile distilled water. Transitory reactions may occur with either drug, but they are generally relieved by the drinking of a glass of water. No serious reaction occurred after almost 8,000 injections. The appearance of the blood and an occasional sedimentation test are usually sufficient to determine the course of the disease. Passive vascular exercise was used, with benefit, for deficient circulation due to thrombotic occlusion of the peripheral arteries. For patients who have recovered completely all treatment may be discontinued, but when smoking is resumed periodic injections should be continued.

Sulfaguanidine for "Bloody Flux."—Lyon and his associates present data on 259 patients who had "bloody flux" and were treated with sulfaguanidine. The drug has proved to be quickly effective and safe for the treatment of such patients in the home, the office and the hospital. They recommend an initial dose of 0.1 Gm. of sulfaguanidine per kilogram of body weight and thereafter one of 0.05 Gm. per kilogram of body weight every four hours for three days and then the same dose every eight hours for two days. If the patient has not recovered by this time and the character of the stool has not changed they advise treatment with sulfathiazole for five days. Sulfaguanidine, because of its freedom from toxic effects, is preferred to sulfathiazole. Its greater safety is not to be overlooked when treatment must be given in the home. The frequency of failure, relapses, second infections and chronic intestinal indigestion has been greatly lowered by sulfaguanidine therapy.

Immunization Against Diphtheria.—Fulton and his co-workers attempted to prevent the spread of diphtheria in a closed or semiclosed community by detecting all carriers and segregating them until the remaining persons acquired an adequate active immunity. They adopted the following method when an outbreak was evident in a school: 1. Swabs taken from the nose and throat of every child and teacher in nonresidential schools and of every person in residential schools were cultured on tellurite blood agar, and diphtheria bacilli were typed. All strains were tested for virulence to guinea pigs. 2. At the same visit all children were given subcutaneous injections of 0.1 cc of alum precipitated toxoid into the left arm and 350 to 500 units of refined diphtheria antitoxin globulin into the right arm. 3. All carriers were isolated or segregated when the results of the swab culture were known. 4. Four weeks later all children, including the carriers, were given 0.3 cc of alum precipitated toxoid into the right arm. 5. All carriers were allowed to return to school two weeks after the second inoculation. They were permitted to mix freely, but in residential schools they were forbidden to participate in games with visiting teams. Any carrier from whom three consecutive swabs negative for diphtheria bacilli when cultured on tellurite blood agar were obtained before the end of the six weeks of segregation was allowed to return to school. This technique was adopted in seven outbreaks of diphtheria. The population at risk was about fifteen hundred. Each outbreak ceased immediately. Only 5 new infections occurred after the first combined injection. The method protects the children at once, and the closing of schools becomes unnecessary.

"Wound Phagedena."—Callam and Duff report 2 cases of a spreading infection of the skin and subcutaneous tissue which arose from an infected wound or sinus. The condition appeared to be one manifestation of a clinical entity, such as postoperative cutaneous gangrene and similar conditions, closely related to the "phagedena" of former times. The infecting agent was an anaerobic streptococcus associated with *Proteus vulgaris*. The condition was so rapidly progressive in 1 case as to be almost inevitably fatal, death occurring on the twenty-first post-operative day. Cure was effected in the other case by wide excision of the lesion.

Frostbite.—Greene states that the conditions of the present war have produced two disorders, immersion foot and shelter foot, and that these are closely related to frostbite and to trench foot. Shelter foot was often seen among shelter dwellers in

London in 1940 and 1941 who sat up all night without compensating rest in a horizontal position during the day. Immersion foot was encountered in persons who, after a shipwreck, spent a long time in waterlogged boats. In shelter foot the swelling of the feet is painless at first. After a while the swelling extends up the leg. The condition did not arise in wardens who, though exposed to the same degree of cold and damp, were frequently on their feet. The wooden bars of the deck chairs used by most of the patients exerted prolonged pressure on the popliteal fossa, causing venous stagnation and increased capillary permeability. Immersion foot is almost identical with trench foot, and its causes are the same, cold, heat after cold, dampness, venous stagnation, wind, anoxia, nutritional deficiency and trauma all may play a part. In true frostbite the immediate cause is cold, frequently aggravated by wind and anoxia. In trench foot and immersion foot dampness, associated with cold and venous stagnation, is probably the most important factor. Though the four conditions have causes which vary in relative importance they act through a common channel—transudation from damaged blood vessels. One can usually prevent them by bearing in mind their causes. Treatment depends on the stage at which it is undertaken. The premonitory symptom of frostbite of the face may be a white patch, which can be cured by the application for a few seconds of a warm ungloved hand. If the foot or the hand becomes numb the boot and sock or glove must be removed and the limb warmed by placing it inside another man's clothing. Rubbing the affected parts is extremely dangerous. If the tissues are dead they are beyond care, but if they are alive warmth, never greater than that of the human body, will quickly restore circulation. If these measures fail, the affected part should be cleansed gently, painted with an active antiseptic (proflavine), wrapped in sterile dressings and in many layers of wool and rested. Antitetanus serum, hot food and drinks, extra clothing, comparative warmth and security and, if the frostbite has occurred above sea level, pure oxygen are indicated. Thereafter, a policy of inactivity should be pursued unless sepsis develops, when it should be treated like sepsis from any other cause. Amputation, without sepsis, is seldom necessary and never urgent. It may be advisable later for esthetic or orthopedic reasons, but the question should be left to the judgment of a surgeon working amid the conveniences of a hospital at home.

Response to Vitamin K.—According to Kark and Souter, of 200 patients suspected of having hypoprothrombinemia the clinical diagnosis in 51 was portal and biliary cirrhosis, catarrhal jaundice, toxic or infectious hepatitis and intense jaundice. In assessing the type and extent of the hepatic disorder in these patients the authors determined the initial level of the blood prothrombin and its character and degree of response after the administration of vitamin K. There were five types of response. In patients with intense jaundice the low blood prothrombin level returned to normal quickly after vitamin K therapy. This favors a diagnosis of obstructive jaundice. Patients with gross hepatic disease failed to respond to vitamin K therapy. Apparently when the blood prothrombin concentration is less than 30 to 35 per cent of normal, advanced hepatic failure is probable. This is a grave prognostic sign. Patients with a lowered blood prothrombin level which rose somewhat but remained fixed at a subnormal level despite repeated administration of vitamin K had acute or subacute parenchymatous hepatic damage of a moderate and variable degree. For patients in whom the blood prothrombin level gradually rose with treatment, coincident with clinical improvement, the diagnosis was infective cholangitis, catarrhal jaundice, acute or toxic hepatitis or obstructive jaundice complicated by an infective process. When the prothrombin level fluctuated at a subnormal level which was above the threshold for hemorrhage, irrespective of therapy, the patients had chronic and long-standing hepatic disease, usually unassociated with jaundice. For patients with hepatic disease who responded incompletely or not at all to vitamin K therapy, transfusion of fresh blood or fresh plasma was the only therapeutic measure that increased the prothrombin concentration of the blood. Such transfusion should be employed, before and after operation, if any surgical procedure is necessary.

*Histoplasmosis in Child: Case. E. Villela and Madureira Pará.—p. 449.

Histoplasmosis in Child.—The case reported by Villela and Madureira Pará is the thirteenth in the medical literature, the fifth of the disease in a child and the first in Brazil. The disease is probably more frequent than is believed. It may be mistaken for visceral leishmaniasis, particularly in regions where that disease is endemic. The disease is fatal. The authors' patient, a boy aged 3 years, lived in unhygienic conditions among dogs and cats. He presented fever and progressive debility for one month. Later there developed diarrhea with blood in the feces and progressive emaciation. The treatment consisted in administering polyvalent antidyenteric vaccines and vitamins A and D. Jaundice and red spots over the body appeared one week before death. The diagnosis was made from the microscopic study of the liver, which was enlarged, waxy in color and friable. The microscopic appearance was typical of histoplasmosis. The parenchyma of the liver presented enormous proliferation of reticuloendothelial cells, which were engorged with *Histoplasma capsulatum*. The monocytic cells were also increased and contained histoplasma. Identification of *H. capsulatum* and its differentiation from leishmania in human tissues is best accomplished by the use of Heidenhain's iron hematoxylin stain, the Giemsa, Gram and Goodpasture stains and the double impregnation method of Del Rio-Hortega. The rarity of histoplasmosis in Brazil may be seen from the fact that, of 186,000 cases in which liver specimens were examined microscopically in the laboratory of the Yellow Fever Service, in only 1 has this blastomycosis been found, while in 131 cases in the same series visceral leishmaniasis was discovered.

Angioneuromatous Tumors. L. Marín Couchot and I. Mena.—p. 719.

Black Widow Spider Bites.—Gajardo Tobar describes observations in 23 cases of bite by the black widow spider, *Latrodectus mactans*, a species found throughout Western America from California to Patagonia. The spiders are most numerous during the dry months. Harvesters, stookers and threshers are most exposed. The bite produces a sensation of lancing, and if the cause is searched for the spider may be found in the clothing. The venom of *Latrodectus mactans* is neurotropic. The bite is followed by a ten minute latent period, after which the local pain recurs and rapidly increases to involve the entire body. Clonic contractions, tremors, spasmodic movements and convulsions follow. The symptoms and pains are intermittent and reach their maximum intensity in the waist, arms and legs. The muscular contractions and the excruciating pain bring about rigidity of the abdomen and of the chest. The patient experiences precordial and abdominal oppression and has the feeling of approaching death. There may be disorientation, hallucinations, delirium, debilitating sweats, profuse salivation and lacrimation. The sensitivity of the skin and the reflexes are exaggerated. The respirations are rapid and shallow. Temporary tachycardia is followed by bradycardia. The arterial pressure increases and later falls. Albuminuria and uremia develop. Intestinal and vesical paralysis develop, and the urinary secretion is diminished. There may be priapism, ejaculations and enuresis. After a few hours the symptoms abate somewhat, only to return in paroxysms. The disorder persists for a week. The convalescence is characterized by physical and mental fatigue. The literature reports fatal cases, but as a rule the patients recover. The bite confers a temporary immunity. In animals the immunization persists for about three months. Persons have been bitten by *Latrodectus mactans* several times and each time have had all the symptoms of poisoning. The treatment is chiefly symptomatic. Hot baths, morphine and atropine sulfate are employed to counteract pain, convulsions and spasms. Sparteine and camphor liniment are administered as cardiac

stimulants. Physiologic solution of sodium chloride, dextrose solution and thiamine hydrochloride are given to counteract the intoxication. It would be most desirable to obtain a specific serum as recommended by Vellard and as prepared by Troise in Argentina. The difficulty in producing a specific serum is the insufficient quantity of venom available.

Gonadal Substances in Ringworm Infections of Scalp.—Yañez and his collaborators point out that ringworm infections of the scalp occurring chiefly in children of school age are more or less contagious, depending on the species of fungus. Infections with some species tend to spontaneous recovery after several months. A cure in one region may be accompanied by infection in another, so that the disorder continues for months or years. To obtain definite results it is necessary to resort to depilation of the scalp. With the exception of favus, ringworm infections of the scalp disappear spontaneously at puberty. This fact suggested the possibility of reproducing the pubertal condition which favors elimination of the parasite by the use of estrogens. Yañez injected estrone into a menopausal woman with tinea tonsurans. The infection disappeared in the course of ten days after the administration of five doses of estrone. The authors administered gonadotropic substance to children with ringworm infections of the scalp. The lesions of tinea showed changes from the fourth or fifth day after the beginning of the treatment. The scales disappeared, the diseased hair fell out and the plaques cleared up. The cure was usually complete on the tenth or the twelfth day. There was no apparent difference in the employment of male or of female gonadotropic substance for persons of either sex. The treatment has been used for 34 children (25 boys and 9 girls); failure was recorded in the treatment of 3.

*Lymphogranulomatosis Maligna During Childhood. A. A. Ferraris.—p. 609.

Pseudomiliary Colloidal Degeneration of Skin: Case. F. Strada and M. Rodeiro.—p. 621.

Lymphogranulomatosis Maligna in Childhood.—Ferraris believes that malignant lymphogranulomatosis is relatively frequent. Of every 4 boys with enlarged cervical lymph nodes 1 was found to have Hodgkin's disease. The author reports observations on 15 children, aged 5 to 12 years; 14 were boys and 1 a girl. Preponderance of the male sex has been observed by other investigators. The onset is generally insidious. There is a gradual enlargement of the cervical lymph nodes; the general condition is impaired; the child lacks appetite, is pale and at times has fever. In 70 per cent of the cases the author observed splenomegaly and in 60 per cent hepatomegaly. The Wassermann and Kahn reactions were negative in all. The Mantoux reaction was positive in only 2 cases; this incidence was approximately that seen in healthy children. The results of Gordon's test at times contradicted the results of the microscopic examination of the nodes. Sternal puncture likewise proved unreliable. Biopsy of an involved node is the most reliable diagnostic method. The treatment consisted in fractional roentgen irradiation; in some cases of late disease sulfonamide derivatives were given. The disease always terminated fatally in one to five years.

Benign Lymphocytic Meningitis. L. Levit, E. S. Weiler and J. Luppi.—p. 1135.

Early Diagnosis of Cancer of Breast.—A hard, woody painless tumor whose borders are vaguely defined, suggests, according to Benzadón, a malignant degeneration of a benign tumor. The hard, woody consistency, which does not permit folding while one picks the tissue up between the hands, is characteristic of malignant growth. Retraction of the nipple may appear later than the aforementioned signs; its presence in

a tumor which shows no signs of inflammation confirms the suspicion of malignancy. Pinching of the skin over a tumor may reveal adhesion to the skin otherwise not observed. This fold test indicates that the neoplasm is malignant. Walther's sign or the wrinkle sign has the same significance. A positive Halsted sign is of great value. A black spot of inklike shadow with irregular outlines on transillumination suggests a malignant tumor. Pneumomastic roentgenoscopy (introduction of air, oxygen or carbon dioxide before roentgenoscopy) can aid in the early diagnosis by revealing a shadow more opaque than the gland with indistinct outlines and at times with diminution of one of the clear spaces. Mammography with the injection of a contrast medium in cases of malignant tumors is not innocuous. Punch biopsy with the finding of malignant cells confirms the diagnosis. A negative biopsy does not establish the diagnosis. Punch biopsy may be valuable in differentiating a solid from a liquid tumor and a neoplasm from a chronic suppurative process. The author does not recommend biopsy; he prefers a complete extirpation of the tumor and a microscopic examination. Early diagnosis is possible, provided the patient consults a physician early enough.

Ascorbic Acid in Mercurial and Bismuth Stomatitis.—Marín observed mercurial and bismuth stomatitis among syphilitic patients. Absence of ascorbic acid from their blood and urine suggested the advisability of administering the acid. His experience with ascorbic acid therapy in 10 cases of syphilis suggests that the acid has a detoxicating effect on the mercurial salts probably because of its reducing action. Ascorbic acid cures mercurial and bismuth stomatitis. It permits continuation of serial mercury and bismuth therapy for patients who do not tolerate compounds of these metals. Injection of large doses of ascorbic acid produces rapid, optimal results; its oral administration is not effective.

*Whooping Cough in Havana: Preventive Vaccination. A. Argudin García.—p. 103.

Vaccination in Whooping Cough.—Argudin García, head of the Municipal Department of Infant Hygiene of Havana, administered vaccines against whooping cough to 1,556 infants who were observed in the department from January to July 1941. The vaccine used was prepared with pure pertussis antigen. It was administered subcutaneously in doses of 0.25, 0.5, 0.75 and 1 cc., with intervals of three days. No untoward reactions occurred. In a large number of children the hemogram after vaccination changed to that of the type of whooping cough, showing acquired immunity. Whooping cough developed in only 5 per cent of the vaccinated children, and it was attenuated. The morbidity and mortality diminished.

Periarterial Sympathectomy for Intermittent Claudication.—Ebbardt reports that a youth aged 19 sustained a fracture of the radius, which was treated with a cast and which healed in a good position. A swelling of the arm remained, and movement of the wrist joint was slightly impaired. Several months later attacks developed during which the hand and arm became blue, cold and insensitive. A thrombotic closure of the axillary vein was considered, but, since the symptoms responded to conservative measures, intervention appeared unnecessary. Two years after the fracture, while swimming, the patient suddenly had a circulatory disturbance in the arm. The member became cold, cyanotic, insensitive and painful. The attack lasted

for half an hour. Considerable exacerbation of symptoms took place. An operation disclosed that the disorder was the result not of venous thrombosis but of a spasm of the vessels which resulted from a chronic induration of the axillary connective tissue. Freeing of the artery failed to improve the circulation. A periarterial sympathectomy was successful in ameliorating the condition. The author does not consider sympathectomy as the procedure of choice for the treatment of intermittent claudication but believes that it is advisable only for some particularly constituted patients.

Tendovaginal Panaritium.—According to Welcker, clinical observation and bacteriologic studies demonstrated the etiologic significance of the subcutaneous panaritium in the development of the tendovaginal abscess. Early and correct surgical treatment of the subcutaneous panaritium is the best prophylactic measure against the involvement of the tendon. Simple opening of the proximal end of the tendon sheath (modification of Iselein's method) as treatment of tendovaginal suppuration of the second and fourth fingers with suspension of the splinted arm produced surprisingly favorable results in cases in which the tendon itself had not become involved. The results of this intervention were especially favorable in regard to functional restoration.

Artificial Changes of Cerebrospinal Fluid (Apart from Admixture of Blood) During Evacuation of Larger Amounts of Cerebrospinal Fluid with Simultaneous Insufflation of Air. E. Lund and A. V. Næsl.—p. 3249.

Adult or Idiopathic Myxedema and So-Called Benign Hypothyroidism.—Jarlöv compares classic myxedema (British Myxedema Commission) and benign hypothyroidism (Hertoghe) and reports 78 cases of so-called hypothyroidism. He concludes that clearcut myxedema is rare. Certain symptoms which must be regarded as symptoms of classic myxedema occur in as many patients with normal basal metabolic rate as in patients with a lowered rate. This is true of the myxedematous habitus, which occurred in only 1 of 7 younger patients and in 4 of 8 older patients with a lowered rate and in 6 of 29 younger patients and in 8 of 17 older patients with a normal rate. Impairment of memory, edema, dryness of the skin, loss of hair, brittleness of the nails, oliguria and amenorrhea were relatively infrequent symptoms. Dryness of the skin affected the younger patients with a normal rate more than any other group. Nervousness and headache were relatively frequent. Constipation and adiposity occurred in more of the groups with a normal rate than in those with a lowered rate. The sensation of cold played a relatively important part in the groups with a lowered rate, but in all the groups it responded well to treatment with thyroid, as did also the tired feeling, important in all groups but wholly absent in some patients with otherwise typical myxedema. The author asserts that adiposity does not play the part in hypothyrotic symptoms formerly ascribed to it. There were relatively many patients with a normal basal metabolic rate and symptoms like those of classic myxedema who reacted so favorably to thyroid therapy that they must be assumed to have had a thyroid deficiency. A lowered rate must therefore be regarded as a symptom coordinated with the other symptoms. In the material all transitions were represented from cases with the symptoms of classic myxedema to cases characterized by only one or a few of these symptoms. Certain cases of asthenia and of stubborn constipation, cases interpreted as of muscular rheumatism, some cases of edema and some others were included. Neither the symptoms named nor the lowered metabolic rate can determine the indications for thyroid therapy or the dose; only the reaction to the substance in each case can be applied as the criterion. He suggests that with the present status of knowledge the designation hypothyroidism be maintained for a number of pathologic conditions having certain common features and forming an indefinitely limited group which can be divided into two indefinitely limited subgroups, malignant and benign hypothyroidism.

Book Notices

Subacute Bacterial Endocarditis. By Emanuel Libman, M.D., Consulting Physician, the Mount Sinai Hospital, New York City, and Charles K. Friedberg, Adjunct Physician, the Mount Sinai Hospital. Edited by Henry A. Christian, A.M., M.D., LL.D. (Reprinted from Oxford Loose-Leaf Medicine.) Cloth Price, \$2.75. Pp. 108, with 19 illustrations. New York, Toronto & London: Oxford University Press, 1941.

This excellent summary of subacute bacterial endocarditis is based in large part on Libman's own long experience with the disease. He writes, for example, that between 1899 and 1930 he had observed at least 1,000 cases. The book is subdivided into sections on definition and classification of endocarditis, classification of bacterial endocarditis, the various aspects of subacute bacterial endocarditis including etiology and pathogenesis, pathology, clinical features, diagnosis, cases of mild subacute bacterial endocarditis, bacteria free stage of the disease, transitional endocarditis, recurrent endocarditis, prognosis, cause of death, prophylaxis and treatment. There is a bibliography of one hundred and ninety-eight references.

There are many pertinent observations concisely made, a few examples of which in the first fifteen pages are:

Bacterial endocarditis is subdivided into acute and subacute bacterial endocarditis. As implied in the terminology, these subdivisions are based on the duration of the disease, the acute form including cases with a course of, in general, less than six weeks, and the subacute, cases with a course of more than six weeks. This differentiation, however, is not an arbitrary one except in certain borderline cases. The two forms of bacterial endocarditis are, as a rule, sharply distinguishable both as to their causative agents and as to their clinical and pathological features. The acute cases are due almost always to pyogenic organisms, while the subacute cases are caused by organisms of relatively low virulence.

Bacterial endocarditis is a terminal or terminating complication in about 10 to 20 per cent of cases of rheumatic heart disease. . . . Subacute bacterial endocarditis occurs much more frequently than acute bacterial endocarditis. In over 90 per cent of the cases the causative organisms are nonhemolytic streptococci, usually the alpha (viridans) and occasionally of the gamma (anhemolytic) variety.

Subacute bacterial endocarditis may appear in the presence of a mixed infection. The most common combination is an endocarditis due to non-hemolytic streptococci with a secondary pneumococcus bacteremia, usually secondary to a lobar pneumonia. We have observed also a secondary implantation of *Staphylococcus aureus* on valvular vegetations due to non-hemolytic streptococci.

Agonal and postmortem blood cultures usually are unreliable.

An adequate quantity of blood must be drawn, at least 20 cc, and a variety of media employed. Aerobic and anaerobic cultures should be made. Since the organisms may enter the blood stream from the vegetations only intermittently, it may be necessary to take repeated blood cultures in order to find the causative organism.

Blood cultures should be observed for a minimum of four days, but it is preferable to keep them routinely for eight to ten days. Sometimes it is advisable to observe the cultures even longer, for, especially after chemotherapy, such as with sulfanilamide or sulfapyridine, growth of the organisms may not be discovered until after two or three weeks. The blood cultures even may remain completely sterile as long as the patient is under treatment with these drugs while positive cultures are obtained subsequently, when they are stopped. Recently reported studies (Strauss, Lowell and Finland) indicate that by the employment of paramino benzoic acid, which inhibits sulfonamide action, it will be possible with such a negative result as is obtained to determine whether bacteria are really absent. This interesting substance has most effect against sulfanilamide, less against sulfapyridine and still less against sulfathiazole.

Usually the site of origin of the endocardial infection is not evident. Clinical observation leads us to the assumption that the portal of infection is, as a rule, about the teeth or in their roots, in the tonsils, in the accessory sinuses or in other parts of the upper respiratory tract.

The sites of localization of the bacterial endocarditis are determined chiefly by mechanical factors. There is evidence that bacteria settle and multiply wherever they are sprayed forcefully on a receptive area.

Active rheumatic fever and subacute bacterial endocarditis may occur simultaneously in the same patient and even on the same valve.

Libman has reported a case in which the disease developed in a mitral valve which had been made insufficient because of infarction of the left posterior papillary muscle due to a coronary artery thrombosis.

Of special interest is the association of subacute bacterial endocarditis with bicuspid aortic valves.

Congenital anomalies are next in importance to rheumatic deformities as predisposing factors of bacterial endocarditis.

The oldest patient we have seen was 74 and the youngest a child of 4. There is no significant predilection as regards sex, but in our experience males are affected somewhat more commonly.

Here and there one might like a little more ample discussion about details, and one might question whether a few of the cases quoted, particularly case 2 and case 3 on page 82, are sure instances of the disease with recovery. However, the volume can be wholeheartedly recommended.

The Story of Clinical Pulmonary Tuberculosis. By Lawrason Brown, M.D. Cloth Price, \$2.75. Pp. 411, with portrait. Baltimore: Williams & Wilkins Company, 1941.

For approximately two decades Dr. Lawrason Brown was regarded as the dean of authorities on clinical pulmonary tuberculosis in this country. Large numbers of tuberculous patients used his book entitled *Rules for Recovery from Tuberculosis* almost as their Bible. Medical audiences throughout the country listened to his addresses, and those who were fortunate enough to attend the Trudeau School of Tuberculosis reveled in his inspiring lectures on the history of clinical pulmonary tuberculosis. This new book will be heartily welcomed by the members of these various groups and by many other readers. The historical material presented is authentic, and Dr. Brown's own views and opinions are of great value, since he was a physician of unusually good judgment. It is particularly fitting that Dr. Homer L. Sampson should have contributed the chapter on x-rays, since it was he who was called almost from his bed as a patient in the Trudeau Sanatorium in 1912 to operate the first x-ray equipment installed in that institution. From that time to the present he has worked unceasingly at this post. No physician ever had a more loyal supporter and collaborator than Dr. Brown had in Dr. Sampson. In many ways and on numerous occasions Dr. Brown expressed his appreciation of Dr. Sampson's work. They labored together in learning how to improve the quality of the finished x-ray plate and film and how to interpret the shadows which it revealed. After the regular day's work they could be found in the x-ray laboratory, working until late at night to develop the roentgenographic phase of examination of the chest. Indeed, they inspected the plates and films of the chests of nearly half a million persons, and from their arduous work came numerous valuable contributions. Twenty years ago Dr. Brown manifested a great deal of enthusiasm for surgical methods in the treatment of pulmonary tuberculosis and was particularly loud in his praise of the splendid work of Dr. Edward W. Archibald of Montreal. They frequently conferred on this subject, and Dr. Brown referred patients to Dr. Archibald when he thought they would be benefited by surgical intervention. He recognized not only the great skill which Dr. Archibald possessed but his studious quality, which caused him to be regarded as one of the best informed chest surgeons in North America. Dr. Archibald's chapter, on the development of surgical methods in treatment, is an important contribution to the book. Dr. Brown spent many years compiling historical material on all phases of clinical pulmonary tuberculosis, and it is fortunate for the medical profession that this has been published in book form so that it will be preserved and available to physicians everywhere. An excellent bibliography is included.

Über Grundumsatz und Sexualhormone nach Kastration: Klinische und experimentelle Studien. Von E. Hart Hansen. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København, 1940. Paper Price, 12 Danish kroner. Pp. 211, with 30 illustrations. Copenhagen: Ejnar Munksgaard, 1941.

Denmark in 1929 was the first state in Europe to introduce castration into the modern administration of justice. There castrates are legally obliged to submit to examinations conducted by the medicolegal council. The problem of the author, who was awarded the opportunity to reexamine castrates in the Institute of Legal Medicine, was to observe (1) the occurrence of castration obesity in legally castrated men in Denmark, (2) the behavior of the basal metabolism in legally castrated persons, (3) the relation between castration obesity and changes in the basal metabolic rate, (4) the excretion of gonadotropin, estrogen and androgen in the urine after castration, (5) the effects produced on rats by the estrogen and androgen detected in the urine and (6) the relation between the results of the hormone analyses and of the determination of basal metabolism and the results observed in routine examinations. The author's conclusions were based on observations on 45 castrated persons, 24 ambulatory, 12 under institutional observation and 9 in an asylum for the feeble-minded. Causes of castration were feeble-mindedness in 14 cases, psychopathy in 18, commitment to an institution in 12 and epilepsy in 1. His control material consisted of 14 healthy men, castrated women and men with other diseases.

Hansen found that castration obesity occurred in only 15.4 per cent of his subjects, proof that weight changes in male castrates are not ordinarily significant. The basal metabolic rate was less than 90 per cent in 6 of 38 castrates. No important information concerning reduced function of the male gonads was revealed by the basal metabolism examinations. Castration obesity and decreased metabolism did not run parallel. Of 38 subjects examined, 1 with castration obesity and 4 without castration obesity showed a decreased basal metabolic rate; 5 with castration obesity and 28 without castration obesity were without a decrease in the rate. An increased excretion of sex hormone occurred after castration of men. Estrogen excretion was less in noncastrated men than in those who had been castrated. The urine of men contained smaller amounts of estrogen than that of women. In general, castrates excreted smaller amounts of androgen in the urine than normal men. Improved methods resulted in an increase in the amount of androgen which could be detected. Injections of androgen into castrated male rats produced an increase in weight of the prostate, the seminal vesicles and the penis. Injections of estrogen into female castrated rats caused doubling of the weight of the vagina and cervix. The results of the preceding experiments were compared with parallel experiments with androsterone in capons.

The author found no difference in the relationship between the results obtained in the determination of the basal metabolic rate and the results of the hormone analysis in subjects with a rate less than 90 per cent and those with a rate greater than 90 per cent. Obesity did not influence the results. These data, while of no value in reexamination of the individual, are in no wise derogatory to the application of castration on a legal basis. The hormone balance of the organism is influenced by post-puberal castration. This is evident from the increased excretion of gonadotropin and the decreased excretion of androgen and estrogen in the urine. The author states that this investigation has revealed no causal connection between androgen secretion and the remains of libido and potency of castrates.

It may be assumed that a metabolism of substances (related to cholesterol and provided with sex hormone properties) takes place in the organism. These substances exert a specific influence on the morphology and function of the secondary sex characters. This metabolism is under the influence of the gonads but does not stop after castration. Finally, the importance of such scientific investigations in a state such as Denmark, where castration is on a legal basis, is stressed.

Chinese Lessons to Western Medicine: A Contribution to Geographical Medicine from the Clinics of Peiping Union Medical College. By I. Snapper, Professor and Head of the Department of Medicine, Peiping Union Medical College, Peiping. With a foreword by George R. Minot, Professor of Medicine, Harvard University, Boston. Cloth. Price, \$5.50. Pp. 380, with 132 illustrations. New York: Interscience Publishers, Inc., 1941.

This book, written in a breezy, narrative style, does not purport to be a systematic study of the diseases characteristic of North China but is rather a record of the impressions of the author, a Dutch clinician with a worldwide reputation, during the first two years following his transplantation to the Peiping Union Medical College. These impressions are, however, in most instances carefully documented from the hospital records and are supported by many excellent illustrations and detailed case records.

Although Peiping is situated at a latitude of 40 north, about the same as that of Philadelphia, its diseases are largely tropical or semitropical, and one is struck, on first visiting the wards of the Peiping Union Medical College Hospital, with the preponderance of patients with acute infectious disorders. Dr. Snapper thus gives due prominence to relapsing fever, typhus and amebiasis, all of which lend color to the practice of medicine in China, but even more to kala-azar, the parasitic disease which places its mark all over internal medicine in North China and which is so frequent that it has to be considered in nearly every case.

The manifestations of cardiovascular disease in North China are considered in detail, and one of the common myths about China, i. e. that the Chinese, owing to the placidity of their dispositions, are not subject to hypertension, is disposed of. Essential hypertension, both benign and malignant, is common.

Arteriosclerosis, however, with the syndrome of angina pectoris and with coronary occlusion and myocardial infarction, is rare, and Dr. Snapper speculates about the relationship of the low cholesterol intake and the consequent low blood cholesterol concentrations in the Chinese to the reduced tendency to lipid infiltration of the blood vessel wall, pointing out at the same time the relatively high figures for the unsaturated fatty acids, especially linoleic and linolenic acids.

There is an extended consideration of the anemias, concluding with the statement that, while macrocytic nutritional anemia is frequent, genuine pernicious anemia rarely occurs. Dr. Snapper also calls attention to the prevalence of diabetes mellitus and rickets, without noting that it used to be said of these disorders, as of hypertension, that they did not occur in China. With the establishment of the Peiping Union Medical College and of its hospital, to which Dr. Snapper refers as now one of the best modern teaching hospitals, the search for these conditions really began, and they appeared with about the same frequency as in the United States.

It is pointed out that every phase of clinical medicine in Peiping is influenced by the peculiar food situation, which leads to general undernutrition, by deficiencies of all the vitamins except those of the B complex. In North China the B complex vitamins are provided by the relatively large intake of a coarse, whole ground millet, in contrast to the diet of polished rice common farther south.

The book should be required reading for any one whose attention, for any reason, is being drawn to the problems of medicine in the Orient.

Xanthoma and Other Dyslipoidoses. By Fred D. Weidman, M.D., I. Napoleon Boston, M.D., Joseph Stokes, Jr., M.D., Howard W. Schaffer, M.D., Walter Freeman, M.D., and F. W. Sunderman, M.D. [Including Reprinted Articles from the Archives of Dermatology and Syphilology, Archives of Internal Medicine, American Journal of Diseases of Children and Archives of Surgery.] Cloth. Price, \$3. Pp. 195, with illustrations. Philadelphia: University of Pennsylvania Press, 1941.

In the introduction Weidman knits the thoughts that prompted these papers and their grouping and stresses the significance of "xanthoses and lipoid disturbances, related diffuse conditions and the growth in knowledge which has been so remarkable that nearly every branch of medicine has become involved to a greater or lesser extent by its ramifications: dermatology, internal medicine, surgery, ophthalmology, pediatrics, otolaryngology, stomatology, physiologic chemistry and pathology." The book contains an index aimed to correlate the biologic phases of xanthoma, particularly the pathologic data, and an article on the pathology of the yellowing dermatoses which is useful from the clinical angle because it will assist in the differential diagnosis of certain of its members from the xanthoma group. This work is recommended to all practitioners in medicine for its excellence and the broad scope of its correlation of xanthoma as a possible manifestation of a medical entity in the skin. The enlarged concept of dermatology, including xanthoma, acute disseminated lupus erythematosus (Libman-Sacks syndrome), the purpuras, tuberculids, drug eruptions and the lymphoblastomas easily fulfil their relationship to medicine in general as cutaneous medicine.

Semiologia do ovário com um estudo particular da citologia vaginal pela método de Shorr. Pelo Dr. Francisco Victor Rodrigues, professor de clínica ginecológica da Faculdade fluminense de medicina, Rio de Janeiro. Cloth. Pp. 286, with 35 illustrations. Rio de Janeiro: A Casa do Livro Limitada, 1941.

This is an excellent study based on the literature and presenting first the embryology, anatomy, pathology and physiology of the ovaries, with few illustrations. After this portion the author goes into the chief material of the volume, which might better be entitled the functional examination of the ovaries. (The author does not include the direct physical examination of the ovaries, as the Portuguese title would suggest.) This is illuminated by detailed studies of 36 of his own cases, including a number of excellent illustrations, some colored, especially of the vaginal smear method of Papanicolaou and Shorr, which the author interprets correctly and makes much use of. In addition to an extensive bibliography which shows an appreciation of the world literature up until late in 1941 the author includes the list of his publications in this general field of gynecology.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

RENAL CALCULI AND SULFONAMIDES

To the Editor—The question of sulfonamide derivatives causing renal calculi has come to my attention recently through the queries of patients and I would appreciate information on the following. Does the formation of renal calculi have any bearing on the administration of sulfonamide drugs? If so, does the drug predispose to the formation of the usual type of stone or do the crystals of the drug collect to form a foreign body in the kidney pelvis? Does the dose of the sulfonamide drug influence the formation of calculi? And, if renal calculi existed before the administration of the drug, would the drug aggravate the condition? If the sulfonamide drugs do form renal calculi, are they permanent or are they dissolved after withdrawal of the drug? What drug of the sulfonamide group is most likely to form crystals in the urine and possibly assemble in the kidney pelvis to form a foreign body visible by x-ray examination? Does the administration of iodized oil for bronchography have any therapeutic value, if so, what and for what?

Louis S. Miles, M.D., Summerville, S.C.

ANSWER—We have no evidence which would indicate that the sulfonamide drugs bear any relation to the formation of renal calculi, either by predisposing toward, or aggravating, existing calculi. The so-called crystals of the drug do not form calculi in the sense with which we usually associate that term, rather they form needles or crystals which in themselves may cause damage or which may "coalesce" to result in larger bodies. Perhaps some consider these larger bodies as calculi, but the term would be a misnomer.

The crystalline bodies which may form following the use of certain sulfonamides tend to disappear on withdrawal of the drug or following the forcing of fluids. However, there are records of necropsies which have shown the masses too large for excretion by the ordinary channels. This explains why so much attention is given to daily examination of the urine when sulfonamide therapy is in progress.

Information does not appear to be available as to the visibility of these bodies by x-ray technique.

The drug which would most likely form crystals in the urine is sulfapyridine.

We have no evidence of any therapeutic value associated with the administration of iodized oil for bronchography.

STERILITY DETECTORS—DIACK CONTROL, STERILOMETER AND ASEPTIC-THERMO INDICATOR

To the Editor—What products are considered reliable for determining the sterility of autoclaved materials?

Ansel Woodburn, M.D., Urbana, Ohio

ANSWER—A number of devices designed to indicate whether or not materials in autoclaves have been sterilized are on the market and in common use. Three of these in particular have been the subject of numerous investigations. The Diack Control is a small sealed glass tube containing a reddish crystalline substance which is supposed to melt or fuse and change color at 121°C. Obviously this reaction is largely or entirely dependent on the single factor of temperature. The Sterilometer is a thermometer-like drawing on a square piece of cardboard, the bulb of the thermometer is said to turn black promptly on exposure to moist heat, and the stem to turn black after subjection to steam at 110 to 120°C for fifteen minutes, or under conditions which insure destruction of all micro-organisms including the spore formers. The Aseptic-Thermo Indicator, which is similar in principle, has a lavender arrow on a green dial pointing to the figure 250°, under the conditions of heat and moisture just described the arrow turns green so as to match its background.

In 1933 T. B. Maath reported a study of Aseptic-Thermo Indicator (*Mod Hosp* 41:112 [Sept.] 1933) in which twenty-five of these devices were tested and were found to turn green only after exposure to 121°C for twenty minutes. The conclusion drawn was that these indicators are satisfactory for testing sterilization with steam under pressure for all uses in bacteriologic laboratories and hospitals. A further investigation of these products was carried out under the auspices of the A. M. A. Chemical Laboratory (*THE JOURNAL*, Nov. 24, 1934 p. 1621). Both the Sterilometer and the Thermo Indi-

cator were found to be efficient in determining sterilization by the autoclave. It was felt that neither type could cause a false sense of security, since whenever the reaction or change was irregular the change was on the side of safety and failure of matching.

These opinions were not corroborated by subsequent investigations, however. Quigley at Johns Hopkins Hospital after extensive studies concluded that the three devices are all unreliable, and their use in that institution was discontinued forthwith (personal communication). Underwood, whose book (*A Textbook of Disinfection*, Erie, Pa. American Sterilizer Company, 1934) is based on investigations carried out in several leading medical centers, contended that none of these indicators are fully trustworthy, although of the three types the Diack Control is the most uniform and generally satisfactory. Underwood cites the work of Lcker, who found that Diack controls fuse at 122°C in two minutes, at 118°C in five to ten minutes and at 115°C in ten to fifteen minutes, that sterilometers change color with the least exposure to steam, the color becoming black with high temperatures, intermediate changes of color being variable and difficult to interpret correctly, and that Aseptic-Thermo indicators show no color changes short of 124°C for fifteen minutes or 121°C for twenty minutes, this requirement being too high since it spoils rubber goods and dextrose solutions. Underwood criticized pasteboard indicators because they show some color changes at less than regulation temperatures, because the color fades somewhat in sunlight, because any hydrogen sulfide gas present may cause misleading color changes (in sterilometers), because the degree of color change requires interpretation and thus adds a factor of uncertainty, and because the cards cannot be extracted from the centers of packages without disturbing the covers and contaminating the contents.

The most damaging evidence against these telltale indicators was submitted by C. W. Walter (*Surgery* 2:582 [Oct.] 1937), who tested one thousand each of the three types. A glass steam pressure chamber was used so that the products could be observed constantly under controlled conditions of temperature, pressure and moisture. Walter found that there were discrepancies between individual Diack controls, that they melt equally in dry and moist heat, and that most of the samples melt in one minute or less at the usual sterilizing temperatures, although in some tests melting was delayed longer than the time usually required for sterilization. Sterilometers were found to have an extremely poor end point of color change. Most of the samples of this product showed complete blackening in less than six minutes, the average time being well below the advertised and published claims, some, however, showed delayed color changes which in practice might have resulted in unnecessary resterilization of the loads. Aseptic-Thermo indicators likewise had poor end points, the majority of samples changing color in less than twelve minutes, although in some change was unduly delayed. On the whole, the indicators were found to be the most consistent of the three types of devices. Walter concluded that the expense of using telltale indicators to certify sterility is not justified because of disparity in individual performance and that the large personal equation in placing and interpreting them makes their use of doubtful value in general hospital practice.

Concerning these devices, Elhott C. Cutler says editorially (*Surg., Gynec. & Obst.* 67:531 [Oct.] 1938) "Various sterility detectors have been devised to assure the surgeon sterile supplies, but such detectors have proved inadequate."

Other methods have been utilized in the effort to insure sterilization by autoclaves. Maximum thermometers proved impractical, since they cannot be placed conveniently inside representative packages of material and since they give no indication of how long the maximal temperature has been maintained. It has been suggested that a thermometer be placed in the discharge line of autoclaves in the belief that the temperature in the sterilizing chamber is certain to be as high as or higher than it is in the exhaust pipe. Timing in such a case should commence when the escaping steam has reached the standard sterilizing temperature (e.g. 121°C). This is a simple method which has much to recommend it. The most satisfactory and reliable detector thus far devised is the recording potentiometer. Thermocouples placed inside representative packages in the autoclave lead to an instrument which records continuously on a time chart the temperatures inside those packages. By this means the desired temperature for the desired length of time inside all the bundles of a load can be virtually assured. Unfortunately these recording potentiometers are rather expensive. For the sterilizing departments of large hospitals an apparatus of proved worth is "Micronax," a multiple recording potentiometer with as many as eight leads,

manufactured by Leeds and Northrop Company, Philadelphia. Walter (*ibid.* 67:526 [Oct.] 1938) has described a control mechanism to be used in connection with a potentiometer which automatically locks the door of the autoclave until standards of sterilization have been met. He claims that this apparatus can be used to eliminate "faulty sterilization due to failure of the sterilizing equipment and ignorance or negligence on the part of the attendant."

It must not be thought, however, that the problem of steam sterilization has been fully solved or that any fool proof method of carrying out the procedure has been discovered. The basic requirement for certain and satisfactory sterilization is that every part of the load, even the center of large, dense packages, should be subjected to moist heat of 121-126 C. for more than fifteen minutes or 115-121 C. for more than twenty minutes, conditions which are known to kill the most resistant microorganisms. The main difficulty lies in adequate expulsion of air from the autoclave chamber and avoidance of pockets of air inside glass jars, rubber gloves and bundles of fabric. Steam and air mix slowly, and diffusion of heat from steam to air requires time. Even after sufficient steam has entered the sterilizer to raise the pressure gage to 15 pounds, air pockets may for a long time show substandard degrees of temperature and moisture. Pressure gages are untrustworthy, therefore, for the purpose of timing steam sterilization, since it is moist heat, not pressure, which kills the bacteria. The best indicator, as has been pointed out, is a recording potentiometer with leads inside large, dense packages and other places where air is apt to pocket or where penetration of steam may be delayed, and the timing of the period of sterilization should not begin until the temperatures in those regions has reached the predetermined standard. Ideally there should be a companion device to indicate whether the heat in those regions is sufficiently moist, since dry heat of 121 C. or less may not kill all the organisms. Some idea of the degree of penetration of steam to the thermocouples can be obtained, however, by noting the lapse of time between closure of the discharge line of the autoclave and the registering of 121 C. by the potentiometer. Ordinarily this requires less than twenty-two minutes (Quigley). If this rise in temperature requires more than twenty-two minutes, it is presumptive evidence that penetration has been delayed unduly and that dangerous pocketing of air has occurred which requires reexamination of the load and a fresh attempt to expel air from the sterilizer.

In conclusion it should be emphasized that pressure steam sterilization cannot be assured without intelligent and conscientious attention to the rules which govern preparation of packages, assembling of loads and operation of the autoclave. Sterility detectors should be viewed as stimulants and correctives, not as substitutes for careful work on the part of the attendant.

CHILBLAINS

To the Editor:—I have been given the following history concerning a woman aged 26 whom I have not seen and who lives in a cold climate: "When she was a little girl her shins were frozen and now in cold weather the shins become red, chap easily and hurt some. In very cold weather they may bleed a little." In your opinion is it possible for these symptoms to be due to "freezing of the shins" twenty years ago?
M.D., California.

ANSWER.—This young woman probably has chilblains or erythema pernio, which usually affects the extremities of subjects with poor peripheral circulation. It appears as various shades of red and purple infiltrated patches and plaques, which are tender and itch or burn, and, characteristically, cold weather incites their presence. The parts are cool to the touch, and the redness disappears on pressure. The manifestations tend to disappear in the warmer seasons. The disease is most prevalent in damp, cold climates. It affects people with the so-called chilblain circulation, which is feeble and is sometimes denoted by cold hands and feet.

In some cases chilblains and its background of impaired circulation becomes difficult to distinguish from livedo reticularis of the extremities, acrocyanosis and erythrocyanosis. A dusky reddish appearance may be imparted by permanently dilated superficial blood vessels, giving a reticulated and marbled pattern. Such changes in the vessels can be produced by syphilis, tuberculosis and toxemias; anomalies of the blood vessels and arteriosclerosis as well as infectious processes may be other causes. A tuberculous background not infrequently may be present in those with poor circulation and subject to frostbite.

Simple pernio needs to be differentiated from lupus pernio, which is a type of sarcoidosis. The latter is a manifestation of tuberculosis, a large number of observers believe. It manifests itself as erythematous symmetrical areas that are infiltrated and

thickened. They vary in color but are often a type of bluish red. They may have dilated blood vessels coursing over them. The diagnosis is readily made by microscopic examination. The tissue has a characteristic appearance. The treatment is with arsenical and gold administrations and exposure to roentgen rays. This type of lupus pernio is the so-called Besnier variety, probably due to tuberculosis.

A second variety of lupus pernio, the Hutchinson type, or chilblain lupus, is a manifestation of lupus erythematosus. This consists of infiltrated erythematous patches and plaques which are aggravated in cold weather. The lesions occur on the face and extremities. Early they look like chilblains but later become more infiltrated and permanent and then look like lupus erythematosus. This type lacks the brownish nodules seen in the Besnier type when viewed through a glass pressed against the surface. Later the plaques are bluish or violaceous and scale, and finally they show atrophy, beginning first at the center. The histologic changes are those found in lupus erythematosus. The greatest difficulty in distinguishing these lesions from ordinary frostbite is present early before tumefaction occurs. Ordinarily, however, chilblains disappears in warm weather, but lupus pernio continues on, though the latter is worse in the winter.

The treatment of chilblains is by attention to the health in general. A tuberculous background, for example, may be present. The circulation should be improved with exercise and locally by friction and massage. Camphor liniment or bay rum may be applied. The extremities may be covered thoroughly with talcum and wrapped in cotton wool held in place by a bandage. The extremities should be kept warm continuously. The administration of arsenic before cold weather sets in is considered prophylactic. The cautious use of acetylcholine and related materials locally as by iontophoresis may be considered as of the newer remedies and not entirely evaluated at present.

ULTRAVIOLET BURNS OF THE EYE

To the Editor:—With the expansion of the heavy industries' the number of cases of ultraviolet burns of the eye has greatly increased. Can any curative substances be used locally in the eye in such cases?

Jonas S. Friedenwald, M.D., Baltimore.

ANSWER.—Inflammation of the eye caused by ultraviolet rays involves only the cornea, causing a characteristic photophthalmia. Only the epithelial cells are involved, although in prolonged exposure the superficial substantia propria may be attacked. The corneal surface is stippled, slightly at first, but, as the latent photochemical reactions develop, the individual epithelial cells extrude their nuclei and finally desquamate. The entire process is characterized by extreme rapidity of cell death and of cell regeneration.

In the beginning of an attack of photophthalmia, iced applications are of some value. One of the more recent corneal anesthetics afford relief, but cocaine is contraindicated. An antiseptic agent to prevent infection of the eroded areas is of definite value. After twenty-four hours, heat hastens epithelial regeneration. There are no known therapeutic agents of curative value; but the condition is self limited, provided there is no intercurrent infection of the corneal surface. (See Duke-Elder, W. S.: *Textbook of Ophthalmology*, St. Louis, C. V. Mosby Company 1:818.)

PHLEBITIS AND CHILDBIRTH

To the Editor:—A patient who has a child nearly 4 years old now desires another. She tells me that she had a severe phlebitis following this birth and wishes to know the possibility of this occurring again. What should be advised?
M.D., Maine.

ANSWER.—Roughly speaking, an involvement of the veins of the lower extremities trebles the incidence of postoperative thrombosis and embolism after abdominal hysterectomy (Barker, N. W.; Nygaard, K. K.; Walters, Waltman, and Priestley, J. T.: *Proc. Staff Meet., Mayo Clin.* 16:33 [Jan. 15] 1941). As a collective review of 179,072 childbirths gave an incidence of 1.3 per cent of thrombosis (Nurnberger, L.: *Verhandl. d. deutsch. Gesellsch. f. Kreislaufforsch.*, p. 101, 1934), a previous thrombosis might approximately result by analogy in a 4 per cent incidence of thrombosis. The patient, then, is taking about the same chance as if she were undergoing an abdominal hysterectomy instead of a childbirth *per vias naturales*.

Cardiac disease, obesity, age above 40, prolonged labor, dehydration, anemia and infection are other predisposing factors. Elevation of the foot of the bed, snug bandaging of the limbs and cautious administration of heparin for seven to ten days after delivery will minimize the recurrence of phlebitis.

SURGICAL ASPECTS OF ACUTE PANCREATITIS

WITH SPECIAL REFERENCE TO ITS FRE-
QUENCY AS REVEALED BY THE
SERUM AMYLASE TEST

ROBERT ELMAN, M.D.

ST. LOUIS

Acute pancreatitis is certainly a dramatic and interesting disease, yet it is often dismissed as unimportant by most physicians because they consider it as extremely rare and usually fatal. In direct contrast to this impression I expect to demonstrate that acute pancreatitis is far from rare and that in its common form it is rarely fatal but subsides spontaneously. The supposed rarity of acute pancreatitis is due to the fact that it is nearly always unrecognized because it mimics other well known acute conditions, both surgical and medical. In many instances the severe pain in the upper part of the abdomen, nausea and vomiting, local tenderness and muscle spasm all point to what is often called a surgical emergency. Indeed the indications for immediate laparotomy seem so clear that many patients with acute pancreatitis are operated on without any suspicion of the real cause of the trouble; the usual tentative diagnoses are perforated peptic ulcer, acute cholecystitis, intestinal strangulation or acute appendicitis. The diagnostic error is first apparent when the expected lesion is not found; however, if the surgeon is persistent and explores the abdomen, the true state of affairs will usually be revealed. Clear or brownish fluid may be seen coming from the lesser peritoneal cavity, and the pancreas, if it is palpated, will feel enlarged and firm, especially at the head of the gland. If the organ is exposed for inspection it will be found to be edematous, usually a little whiter than normal, and may exhibit tiny areas of fat necrosis over its surface. Occasionally, however, the color is darker, as if suffused with blood. Only in the severe type (called acute necrosis of the pancreas), which fortunately is rare, is there hemorrhagic fluid in the abdominal cavity as well as widespread fat necrosis. This experience with acute pancreatitis is common with most surgeons. As expressed by Finney¹ at the Union Memorial Hospital in Baltimore, where 21 patients with acute pancreatitis were operated on, "At most we have diagnosed 2 correctly from a clinical standpoint and I am not sure about them."

¹Max Ballin Lecture, delivered at the Institute of Art, Detroit, Nov. 26, 1941.

²From the Department of Surgery, Washington University School of Medicine, and Barnes and St. Louis City hospitals.

³I. Finney, G. G., in discussion of paper by Morton, J. J., Jr., and Widger, S. W.: *Ann. Surg.* 111:802 (May) 1940.

Acute pancreatitis occurs also without raising the question of an acute surgical emergency, because it may simulate purely medical diseases commonly seen by internists. In such cases the presumptive diagnosis is usually acute coronary disease, biliary colic or occasionally tabetic crisis. The fact that the attack subsides promptly often serves to remove the need for any further diagnostic procedures and lulls the physician into a false sense of security that the first impression was correct. It is true that if biliary colic is suspected the diagnosis of cholecystitis is often confirmed when subsequent studies show that the gallbladder is diseased and cholecystectomy advised. Unfortunately, the diagnostic error in many such cases confronts the physician only after cholecystectomy has been performed and the patient returns with recurrent attacks of similar nature occurring within a few weeks or months after operation. Now the surgeon may take the blame for the recurrent attacks, especially if stones were present in the gallbladder, by confessing to the possibility of having missed a stone in the common duct. He may even cheerfully offer to operate again and look for the stone. If he does not find a stone, a T tube is usually inserted in the common duct and the diagnosis in the file of the patient's history becomes "postcholecystectomy syndrome."

Up until a decade ago there was no reasonably certain way of making a clinical diagnosis of acute pancreatitis, and this is, of course, the reason it was seldom recognized and therefore considered rare. Indeed, our sole knowledge of acute disease of the pancreas was furnished by pathologists and to a lesser extent by surgeons. The best known type of acute pancreatitis, acute necrosis of the pancreas or acute hemorrhagic pancreatitis was summarized by Reginald Fitz² on the basis of autopsy findings in his classic papers published in 1889; he described and classified the various lesions which are included under these terms. Surgeons also encountered this lesion and soon recognized its severity and the high mortality that followed operation. However, the usually fatal type of disease which Fitz described was extremely rare and for this reason aroused little clinical interest. I shall have relatively little to say, therefore, of acute pancreatic necrosis, but more of the subsiding or transient type of acute (nonhemorrhagic) pancreatitis which is common and rarely fatal.

In 1927 I became interested in the pancreas and largely for diagnostic reasons studied in the serum the pancreatic ferment amylase by a viscosimetric method. My first patient who presented a high serum amylase (thirty times normal) was the mother of a colleague, who had an attack of severe abdominal pain and circulatory collapse, which ended fatally within twenty-four hours; at autopsy there was an intense

²Fitz, R. H.: *Acute Pancreatitis*, Boston & M. S. J. 120:81F, 205 and 229, 1889.

acute hemorrhagic pancreatitis. Other patients were encountered with a high serum amylase, three of whom were later shown to harbor pancreatic cysts, although the values were not as high.³ Soon afterward I operated on a patient with supposed biliary colic whose serum amylase was extremely high (twenty times normal). At operation I found gross evidence of acute pancreatitis, biopsy of the pancreas showed interstitial changes of acute inflammation. On consulting the literature I was able to find, without much difficulty, nearly 40 cases of acute nonhemorrhagic pancreatitis, nearly all encountered more or less accidentally by surgeons while operating on patients with acute disease of the abdomen, supposedly due to other lesions.⁴ The first reference I could find of acute pancreatitis without necrosis was to a patient operated on by Dr W S Halsted⁵ in 1890. The preoperative diagnosis was intestinal obstruction; nothing was done at operation and the patient recovered. In 1922 Zoepffel,⁶ a German surgeon, operated on 4 patients because of acute manifestations within the abdomen and found changes in the pancreas which were quite unexpected. Zoepffel called the lesion acute edematous pancreatitis because he observed the extreme edema surrounding the gland. All 4 of his patients recovered, although nothing specially was done at operation to the pancreas except to take a specimen for biopsy.

Armed with a simplified method⁷ of determining amylase and convinced of the frequency of nonhemorrhagic pancreatitis, I became suspicious of all patients entering the hospital for emergency treatment of acute pain in the upper part of the abdomen, blood was examined for its content of amylase in a series of such patients. Many of them showed high amylase values, at first I operated on these patients and found the changes in the pancreas already noted. It soon became apparent, however, that the attacks, dramatic as they seemed on entrance, rapidly subsided, and often in twelve hours the patient seemed entirely well in contrast to the dire situation the night before.

During the past ten years many more similar observations were made at the Barnes Hospital and St. Louis City Hospital, details of which may be found in several publications during this time.⁸ With the use of serum amylase determinations at Barnes Hospital, the number of diagnoses of acute pancreatitis has increased by several hundred per cent. At the St. Louis City Hospital 65 cases were recognized during the past five years, whereas before the use of the amylase test such a diagnosis appeared only a few times a year and then nearly always it was based on observations made at autopsy. Indeed, the incidence of acute pancreatitis was about half of that of perforated peptic ulcer and one tenth of that of acute appendicitis at the latter hospital. Similar observations have been made in other clinics. This situation is not surprising when one realizes that the

clinical picture of acute pancreatitis mimics so closely other acute conditions of the abdomen that often the diagnosis cannot be made without the aid of the blood amylase test. The following is a typical recent experience.

A salesman aged 31, unmarried, was admitted because of an emergency with the history that thirty hours before his entrance he was seized with sudden, constant epigastric pain with no radiation and that he had vomited on several occasions after onset of the pain. Previous to this seizure he had been relatively well, except that for the past five months he had suffered from similar but milder episodes of pain lasting several days, with complete freedom of symptoms between attacks. He received some relief by taking sodium bicarbonate and occasionally by consuming food. Several physicians who examined him stated that he had a duodenal ulcer. On admission the patient was severely prostrated but was not in shock and complained bitterly of pain in the midepigastrium. Although a roentgenographic examination did not show air under the diaphragm, the local signs (severe local tenderness and muscle spasm) were so characteristic of peritoneal irritation that it seemed certain that he had either an acute cholecystic obstruction or a perforated peptic ulcer. Because of the possibility of pancreatitis the amylase in the blood was determined. Nevertheless, the patient was prepared for operation, however, promptly after the administration of fluid there was almost a complete relief of pain. Moreover, the local conditions subsided so rapidly that operation was not carried out. This decision was made easy by the fact that the blood amylase examination was reported as 1,500, the normal being about 100. Several days later the blood amylase had returned to a normal value. In view of his past history a complete gastrointestinal series was done. No evidence of ulceration or other abnormality was found. The cholecystogram was of great interest and showed merely a faintly but very definitely visualized gallbladder. The patient was discharged from the hospital and on a dietary regimen has thus far remained well.

This experience is an instructive one because it emphasizes again the fact that it is easy to overlook the possibility of acute pancreatitis and illustrates, therefore, the ease with which such a diagnosis may be missed and an unnecessary operation carried out. It may be missed because the blood amylase test is really the only certain method of diagnosis. May I also emphasize that it is of value only during the acute manifestations. If we had waited a day or two before examining this patient's blood the value for the amylase would have been normal and we never would have known that he actually was suffering from pancreatitis unless, of course, we had operated and found the lesion. The curve of amylase is usually a characteristic one, high at the beginning of the attack but falling very rapidly to normal, as has been illustrated in many publications both from our clinic and elsewhere. Nevertheless, the question is often raised and I must emphasize again that in the typical case serum amylase measurements are of no value whatever unless carried out shortly after the patient's acute symptoms begin. This is particularly true, of course, when the attack is relatively mild in its severity, because in these instances the elevation of the serum amylase, though striking and pronounced, may be of only twelve to twenty-four hours' duration.

Is there actually any sound clinical basis for a bedside diagnosis of acute pancreatitis? I am afraid that I must answer this question in the negative. In spite of my own observations of a good many cases over many years, I believe that such a clinical diagnosis is often impossible. Indeed, one must consider such a diagnosis in every patient with acute pain in the upper part of the abdomen, even though he seems to be presenting the typical clinical picture of the following con-

ditions: perforation of a peptic ulcer; acute intestinal obstruction; acute cholecystic obstruction or acute cholecystitis; coronary disease; biliary colic; acute appendicitis; tabetic crisis. Indeed, I may say that any patient with severe, pronounced abdominal pain, particularly when it is located in the epigastrium, should be suspected of having acute pancreatitis. If the blood is examined promptly in such cases, many cases of acute pancreatitis will be detected; certainly the test will enable one either to make such a diagnosis or to exclude it. Obviously, the last result is most frequent, and one is thus enabled to exclude the diagnosis of acute pancreatitis and consider other possibilities. On the other hand, a positive test will lead to a diagnosis of acute pancreatitis and thus exclude other lesions for which an immediate abdominal operation might have been carried out; this is especially important because a diagnosis of acute pancreatitis does not call for immediate operation.

TREATMENT OF ACUTE PANCREATITIS

Once a diagnosis of acute pancreatitis is made at the time of the acute attack, the surgeon must then decide whether the patient is suffering from acute nonhemorrhagic pancreatitis or whether the lesion is a true necrosis of the pancreas. Since operation is not urgent, the patient can safely be observed. If the patient has acute nonhemorrhagic pancreatitis, the attack will subside promptly and further examinations can be carried out later. On the other hand, if the patient is suffering from a true necrosis of the pancreas, the attack will not subside and prolonged nonoperative therapy may end in a fatality. It is in the latter group of patients, fortunately very rare, on whom I believe operation should

be carried out at an appropriate time, because without operation the mortality approaches 100 per cent. It is difficult to state what this appropriate time will be, but certainly sufficient time must be allowed for adequate preparation of the patient, perhaps for at least several days. Only rarely is it possible for an acute necrotic process in the center of the abdominal cavity to be relieved spontaneously, usually by sloughing of the necrotic organ or drainage of an abscess into the lumen of the intestine or to the exterior. At operation the lesion must be attacked at its origin; the surgeon opens the lesser peritoneal sac and allows escape of infected and necrotic material to the outside by drainage of this cavity. Drainage of secondary abscesses, which usually develop by extension from the lesser peritoneal cavities, is usually insufficient. Cholecystostomy is also advisable in these patients in order to divert the flow of bile which seems to be a factor in the development of pancreatitis by reflux into the pancreatic duct. Many years ago I operated on several such patients who survived and are living today. I must confess that during the past few years, influenced largely by the popularity of the so-called conservative treatment of all types of pancreatitis, we have refrained from operating on these patients. As a result, I have seen 6 such patients during the past

five years at the autopsy table. Some of them, I am sure, might have been saved if they had been operated on, since they were in the hospital for several weeks before the fatal outcome. It is well to emphasize also that in patients with hemorrhagic as well as in those with nonhemorrhagic pancreatitis the blood amylase tends to fall after the initial rise. The fall in the former case, however, is not due to a subsidence of the process of inflammation but rather to a destruction of the gland which manufactures amylase. A fall in the level of blood amylase, therefore, must not be taken as an indication that the process is subsiding. This decision must be based on the clinical manifestations.

What is done when the attack of acute nonhemorrhagic pancreatitis has subsided and the patient after the course of a day or two or more feels perfectly well? It has been our policy to study these patients at leisure, usually by carrying out a complete gastrointestinal examination as well as a cholecystogram. If, as the result of such examinations, an operation is indicated (usually cholecystectomy), it is carried out. In many of these cases removal of a diseased gallbladder and stones will result in a complete relief of further

Characteristic serum amylase curves in four groups of patients with acute interstitial pancreatitis: A, with normal gallbladder; B, with pathologic gallbladder; C, following cholecystectomy; D, with condition of gallbladder unknown.

attacks. In certain cases cholecystectomy is followed by a recurrence of the attacks of pancreatitis. This experience has stimulated attempts on the part of surgeons to do something at the time of operation which might prevent these recurrences. Indeed, this problem also arises when a patient who has had a previous cholecystectomy returns with recurrent attacks of pain which for the first time are shown to be due to acute pancreatitis. The same problem is presented by the patient with repeated attacks of acute pancreatitis who shows no evidence of a surgical lesion for which an abdominal operation is indicated. The problem, though difficult, is usually hopeful because there seems to be a natural tendency for the attacks to disappear eventually. I wish to make several suggestions which I have found are useful. In the first place, glyceryl trinitrate, $\frac{1}{100}$ grain (0.0006 Gm.), placed under the tongue and repeated in a few minutes shortly after the onset of the attack will often result in dramatic abortion of the attack. This remedy, however, must be used promptly; if the attack has been present for a number of hours the drug usually fails. For this reason, the patient is asked to carry a number of these tablets to be taken as soon as the attack begins. The mere possession of these tablets, once they have effected relief of the pain, often gives the

individual a great deal of confidence, that the fear of attacks may thereby be overcome has perhaps in itself some therapeutic value. Other drugs have been recommended for the relief of pain during the attacks. However, most of them are apt to be disappointing. This is true of morphine as well as epinephrine and ephedrine.

The patient who has had several attacks of acute pancreatitis should also be placed on a regimen which has as its purpose the maintenance of a more or less constant flow of bile and the avoidance of any storage of bile for long periods of time in the gallbladder. This may be achieved by a regimen of small frequent feedings and the avoidance of any large meals with necessarily long periods afterward when no food is ingested. In this way many patients may enjoy long remissions.

In the really refractory cases of acute pancreatitis, particularly those in which a previous cholecystectomy has been performed, the problem is more difficult. Many of these patients have had various procedures performed, such as a T tube drainage of the common duct, in an attempt to prevent such attacks. Dilation of the sphincter of Oddi has been advised and performed. Cutting of the sphincter has also been carried out. These last two procedures are based on the theory that pancreatitis is due to a sphincter spasm which converts the biliary and pancreatic ducts into a common channel and that bile acts as an irritant when it enters the pancreas. If this is indeed true, a more obvious solution would be the transplantation of the common duct to another site in the duodenum. I have never heard of this procedure being done and have never done it myself. Perhaps it should be done in refractory cases of acute pancreatitis which do not respond to other therapy.

There are other types of pancreatitis which have surgical interest and can be detected and the course of the disease followed by measuring the blood amylase. These conditions are much less common than the clear-cut instances of acute nonhemorrhagic pancreatitis thus far discussed. For example, patients have been studied with evidence of subacute pancreatitis which follow an atypical course. In other patients a peptic ulcer may slowly perforate into the pancreas and produce an inflammatory reaction reflected in elevations of the blood amylase. Such cases require further study, I have seen very few of them. There is a suggestion which I should like to make, however, in regard to the early diagnosis of carcinoma of the head of the pancreas. Having observed several jaundiced patients with increased blood amylase values who subsequently were shown to have carcinoma, I suggest the more frequent use of this test early in the course of unexplained jaundice. If the tumor obstructs the pancreatic duct, the rise in blood amylase will be prompt, however, with complete obstruction a return to normal occurs within a few weeks. Indeed, in nearly all late cases of carcinoma of the head of the pancreas that I have studied the blood amylase was normal or below normal.

SUMMARY

Physicians are urged always to consider the pancreas as a cause of severe pain in the upper part of the abdomen. The frequency of acute pancreatitis is not generally realized because this disease so mimics other acute conditions that a clinical diagnosis can seldom be made without the serum amylase test, which reveals a high value soon after the onset of the attack. The clinical manifestations of acute pancreatitis are usually those of an acute surgical condition within the

abdomen such as perforated peptic ulcer, acute intestinal obstruction, acute cholecystitis and acute appendicitis, so that often emergency operations are needlessly performed. In other instances acute pancreatitis may be regarded as a coronary attack or biliary colic and is a cause of the "postcholecystectomy" syndrome. Treatment is conservative at the outset of the attack, if the manifestations subside promptly, as they usually do. A subsequent study may reveal the need for operation, usually cholecystectomy, if the manifestations do not subside, necrosis of the pancreas (a rare event) is suspected and operation planned for drainage of the lesser peritoneal cavity. The treatment and prevention of the individual attacks of acute nonhemorrhagic pancreatitis thus far is purely medical.

THE USE OF SULFAGUANIDINE IN THE TREATMENT OF DYSENTERY CARRIERS

LOWELL A. RANTZ, M.D.

AND

WILLIAM M. M. KIRBY, M.D.

SAN FRANCISCO

A chemical for the treatment of infections, such as bacillary dysentery, which are limited to the gastrointestinal tract should have certain properties. It must dissolve in the bowel content in a concentration adequate to inhibit the multiplication of, or to kill, pathogenic organisms and must be harmless to the human or animal host. No intestinal antiseptic has, in the past, fulfilled these requirements. The use of the sulfonamide drugs has become firmly established in the treatment of various infections but the rapid and complete absorption of these chemicals from the gastrointestinal tract has made them valueless in the therapy of local enteric infections. The report by Marshall Bratton White and Litchfield,¹ describing the properties of sulfaguanidine, the analogue of sulfathiazole and sulfapyridine, was received, therefore, with great interest. This drug was found to be soluble in water in amounts sufficient to cause adequate bacteriostasis of intestinal pathogens but was poorly absorbed from the bowel so that a high concentration in the intestinal content and a low concentration in the blood and tissues was readily attained. Animal experiments suggested that the number of coliform bacteria in the feces of mice, dogs and monkeys² could be reduced by the administration of sulfaguanidine.

In vitro experiments³ have demonstrated that this chemical strikingly inhibits the growth of strains of Flexner, Sonne and Shiga varieties of dysentery bacilli and also of *Salmonella cholerae suis* and *Salmonella paratyphi A* but is ineffective against other organisms in the *Salmonella* group.

It has been suggested that the apparent failure of absorption of sulfaguanidine might be due to a removal of the drug from the blood stream by the liver and a return of the material to the gastrointestinal tract.

in the bile. Hubbard and his associates⁴ have recently studied this possibility and have shown that the concentration of the drug in the bile was sufficiently low to exclude the possibility of any important degree of reexcretion into the intestine.

This experimental evidence logically suggested a trial of sulfaguanidine in acute bacillary dysentery. A group of 17 children were treated by Marshall, Bratton, Edwards and Walker,⁵ who felt that the results obtained were satisfactory, especially if chemotherapy was begun before the third day of the disease. The drug was found to be very poorly absorbed from the gastrointestinal tract, as had been anticipated from the previous animal experiments. The use of sulfaguanidine in the treatment of bacillary dysentery has also been described by Lyon,⁶ who studied two groups of 23 patients, one of which was treated with this drug. Bacteriologic diagnosis was made in only one third of the cases. Clinical improvement occurred in 18 of the treated cases within forty-eight hours, and recovery was well established in a few days. Fever continued, in the control group, for two weeks in association with bloody purulent diarrhea and loss of weight and strength.

The course of chronic bacillary dysentery in 2 babies was not altered by the exhibition of sulfaguanidine,⁵ and no other trials of the use of this agent in the treatment of chronic cases of this disease, or of healthy carriers of dysentery bacilli, appear to have been reported. The presence of typhoid bacilli in the gall-bladders of carriers of this organism may cause local chemotherapy to be ineffective in the control of this condition. Eradication of these bacteria from the stools of 1 patient following the administration of sulfaguanidine has been described.⁷

In the treatment of acute bacillary dysentery, sulfaguanidine has usually been administered in an initial oral dose of 0.1 Gm. per kilogram of body weight, to be followed by 0.3 Gm. per kilogram in divided doses every twenty-four hours until clinical improvement has occurred. The dose is then halved and continued for at least three days.

The toxic manifestations that may be observed in association with the use of sulfaguanidine are similar to those encountered with the other sulfonamides. Fever, skin rash, conjunctivitis, anemia and crystalluria have been described but have not been severe in any case.⁸ No signs of toxicity or postmortem evidence of tissue damage were observed in monkeys treated with large doses for one month.⁵

PRESENT STUDY

Dysentery bacilli were isolated from the stools of 10 employees of a San Francisco hospital during a recent survey. These persons and one other man were selected for treatment with sulfaguanidine in an attempt to eliminate dysentery bacilli from their stools.

The accompanying table summarizes the data pertinent to the study and treatment of these patients. All of the isolated organisms were nonmotile and fermented mannite and xylose. Only one failed to attack dulcitol. Agglutination tests were performed and the

results are shown in the table. Most of the strains were agglutinated by antisera for *Shigella alkalescens* and the Flexner X and V varieties.

These are, in general, the characteristics of *Sh. alkalescens*.⁹ The pathogenicity of this variety of dysentery bacillus in man has only recently been established in spite of its close antigenic and cultural relationship to the usual Flexner types. The failure of many laboratories to perform adequate differential tests accounts, in part, for the slow recognition of the bacillus. In this clinic *Sh. alkalescens* has been isolated from examples of acute and chronic dysentery and is more frequently recovered than any other variety of dysentery bacillus.

About half the patients had had mild gastrointestinal symptoms before treatment. These were rather non-specific in character, chiefly abdominal cramps and diarrhea. Patient 5 had had several loose bowel movements daily for more than a year. A course of atabrine was administered for the purpose of eliminating an infection with *Giardia lamblia*, but he continued to have four or five stools a day, from which many dysentery bacilli could be isolated before treatment was begun. Each patient received 12 Gm. of sulfaguanidine^{9a} daily for from two to six days. The total amounts varied from 16 to 84 Gm., the average being about 50 Gm. The drug was discontinued voluntarily on the second day, because of nausea and vomiting, by 1 patient. All the others completed the course prescribed.

Stool specimens were collected in each case on every second or third day during the first ten days of observation after treatment was begun and then at

approximately weekly intervals. Sulfaguanidine was demonstrated in the stools by qualitative tests for four to five days after the cessation of treatment. Cultures were made of every stool. The amount of sulfaguanidine in the blood of each patient was determined on the third or fourth day of treatment by the method of Bratton and Marshall.¹⁰

RESULTS

Dysentery bacilli disappeared from the stools of 9 of the treated patients during the period of sulfaguanidine administration. Repeated culture of the stools of these persons over an interval of from one to three months has failed to disclose pathogenic organisms on any occasion. In the other 2 cases, treatment was undertaken on three occasions, with progressively larger amounts being given. After the second and third courses of chemotherapy the dysentery bacilli disappeared from the stools of these patients, only to return shortly after the withdrawal of the drug. Patient 5 had symptoms which appeared to be due to chronic infection with dysentery bacilli. Since treatment, his diarrhea has disappeared, his appetite has improved and he has gained weight.

Certain of the treated patients have stated that symptoms referable to the gastrointestinal tract were less severe following treatment with sulfaguanidine. The nature of these complaints is such that evaluation of this observation is impossible.

Few toxic manifestations were noted. Nausea and vomiting occurred in case 1 after 16 Gm. and in case 3 after 48 Gm. of the drug had been administered, but these symptoms were neither severe nor prolonged. Five subjects had slight to moderately severe headaches, lasting twenty-four to forty-eight hours. No drug fevers, rashes, hematuria, oliguria or anemias developed. In general, the subjects were all able to remain ambulatory and to work throughout the treatment.

The amount of sulfaguanidine in the blood was consistently small. The variation was from 0.5 to 5 mg., with an average of 2.22 mg. per hundred cubic centimeters of blood. Sulfaguanidine could be detected in the stools for about five days after treatment was discontinued.

COMMENT

Little is known of the incidence of healthy dysentery carriers among civil groups. It is becoming apparent, however, that bacillary dysentery is an important problem in the United States. Felsen¹¹ has pointed out that this disease was reported sixteen times as frequently in 1937 as in 1933. Inexpensive transportation, leading to a shifting population, and congestion in urban areas may be partially responsible for this increase.

It is often difficult to distinguish clinically between healthy carriers and patients with mild chronic bacillary dysentery, since functional complaints of the former may be identical with the symptoms of organic disease of the latter. Felsen,¹² in a follow-up after the Jersey City epidemic of acute bacillary dysentery in 1934, found that 10 per cent of the patients had persistent complaints varying from mild diarrhea and abdominal cramps to severe forms of regional ileitis and ulcerative colitis. About half of the patients treated with sulfa-

guanidine during the present study had had mild symptoms referable to the gastrointestinal tract, and some felt that they were benefited by treatment. All but 1 should probably be regarded as healthy carriers.

In general, the results of treatment of this group of dysentery carriers with sulfaguanidine have been very encouraging. The stool cultures of 9 of the 11 patients became negative during treatment and have remained so for periods varying from thirty to ninety days. The reason for the failure in the other 2 is not clear. It may be significant that the organisms isolated were serologically different from most of the other strains.

The daily amount of sulfaguanidine administered was smaller and the duration of treatment was shorter than that suggested for acute dysentery, but effective concentrations in the intestine were attained in most instances. A few toxic reactions occurred, but the patients were all able to remain at work while taking the drug.

Dysentery bacilli may not always be so easily eradicated from the stools by the action of chemotherapeutic agents. The organisms isolated from the patients included in this study were closely related biochemically and serologically and were somewhat different from the typical Flexner varieties. They may have been unusually sensitive to the action of sulfaguanidine.

Insufficient clinical and experimental data are available to determine accurately the value of sulfaguanidine in acute bacillary dysentery. Administration of the drug early in the disease appears to have a favorable influence on the course of the infection. That this chemical exerts a profound bactericidal effect on some bacilli of the dysentery group is indicated by the rapid and permanent elimination of these organisms from stools of the carriers described in this study. A similar action should occur to some degree in cases of acute infection with resulting cure or amelioration of the disease. The observations reported in this paper, therefore, provide additional evidence that sulfaguanidine is an effective agent to be used in the treatment of acute and chronic bacillary dysentery.

The healthy carrier of dysentery bacilli is probably the source of most cases of sporadic infection.¹³ In closed groups, such as hospitals, prisons and army camps, such persons at work in the kitchen are frequently responsible for the outbreak of serious epidemics. One of the most difficult problems arising in the control of such epidemics has been the absence of any satisfactory method for rendering the discovered carriers noninfectious. If the satisfactory results obtained in the treatment of carriers reported in this study are extended and confirmed, sulfaguanidine will become a valuable adjunct to the control of the spread of bacillary dysentery both in civil life and in the armed forces.

SUMMARY AND CONCLUSIONS

1. Eleven patients, from whose stools dysentery bacilli have been repeatedly isolated, have been treated with sulfaguanidine. About half had mild gastrointestinal complaints, but, with one exception, they are all regarded as healthy carriers.

2. In 9 of the 11 cases, dysentery bacilli disappeared from the stools during treatment and have not returned over periods varying from thirty to ninety days. This result was not obtained in 2 instances after three courses of treatment.

13. Zinsser, Hans, and Bayne-Jones, Stanhope: *Textbook of Bacteriology*, New York, D. Appleton-Century Company, 1929, p. 545.

3. All patients remained ambulatory and continued work while being treated. Few toxic manifestations were noted.

4. These favorable results suggest that further clinical trials are indicated both in healthy carriers and in cases of chronic bacillary dysentery.

5. This drug, which is adapted for use in ambulatory patients, may become a valuable adjunct to the control of the spread of bacillary dysentery, both in civil life and among the armed forces.

CONTROL OF CROSS INFECTIONS OF THE RESPIRATORY TRACT

IN A NURSERY FOR YOUNG INFANTS: A PRELIMINARY REPORT

L. W. SAUER, M.D.

L. D. MINSK, M.D.

AND

I. ROSENSTERN, M.D.

EVANSTON, ILL.

The adoption of the Dick aseptic nursery technic¹ at The Cradle in 1929 practically eliminated hand borne cross infections, such as enteritis and impetigo. Figure 1 illustrates the effect of this technic on the number of deaths due to enteritis contracted after admission. During the six years prior to the introduction of this aseptic technic (1923 to 1928) a total of 942 infants was admitted. There were 55 deaths, 53 due to enteritis. In 40 of the fatal cases infection was contracted after admission. During the twelve years since the introduction of the aseptic technic 3,132 infants have been admitted. There were 26 deaths, 6 due to enteritis. In no case was infection contracted after admission. The total mortality rate before the introduction of the aseptic technic was 5.8 per cent and after its introduction 0.8 per cent.

There remained, however, the problem of the respiratory cross infections. Nine infants died from infections of the respiratory tract after the introduction of the aseptic technic. Seven of them contracted the infection after admission. Figure 2 demonstrates the incidence of cross infection of the respiratory tract in infants during the last two years in the old building. Although there were seasonal differences, some infections were present at all times of the year. Thus in 1938 there occurred a midsummer infection of the respiratory tract involving all but 1 infant of a twelve crib unit and six attendants.² The epidemic was introduced by an infant admitted with a cold. In 1 of the cases of secondary infection fatal bronchopneumonia developed.

Fig. 1.—Cases of fatal enteritis contracted after admission before and after introduction of aseptic nursery technic.

A new building was erected in 1939 to investigate newer principles in the control of air borne infections: air conditioning, germicidal lights and mechanical barriers. This building was divided into three units of twelve cubicles each.

The cubicles in the control unit are separated from one another by complete partitions but are open at the front. Each cubicle is air conditioned with 100 per cent outside air. The air, at a temperature of 75 F. and a relative humidity of 40 per cent, enters near the ceiling and leaves near the floor. There is a complete change of air every six minutes. Thermostats are placed to maintain a constant temperature throughout the unit.

The only principle applied in this unit to prevent air borne infections is that of air conditioning.

The light unit (fig. 3) was designed by William F. Wells,³ who had made important contributions on light as a bactericidal agent. This unit is air conditioned like the control unit; in addition, germicidal lights^{3a} are placed above the open end of each cubicle so that a vertical curtain of light is thrown across each entrance. Six of these cubicles are separated by partitions from ceiling to floor; in the other six cubicles light curtains replace alternate solid partitions. Ventilation tests of the bactericidal tightness of the light curtains showed that about 99 per cent of the test organisms were killed as they passed through the light barrier. The light curtains are designed so that only a harmless fraction of the rays reaches the corner of the cubicle where the head of the infant is exposed. The nurses' eyes are protected by head shields and goggles. The spectrum band of this light differs from the customary ultraviolet in that approximately 90 per cent of its rays are of 2,537 angstrom units. Favorable results with the application of germicidal lights in infants' and children's wards and schoolrooms have been reported by McKhann, Steeger and Long; del Mundo and McKhann; Wells, Stokes, Wells and Wilder; Barenberg, Greene and Greenspan, and Greene, Barenberg and Greenberg.⁴

The barrier unit (fig. 4) was designed by James A. Reyniers,⁵ who had made important contributions to the

control of air borne cross infections with the aid of air conditioning and mechanical barriers. This unit contains twelve completely closed cubicles, each provided with individual air conditioning. A tightly fitting swinging door separates each cubicle from the corridor

Fig 3—Light unit, there are germicidal light barriers at each cubicle entrance and between alternate cubicles

of the unit. Six cubicles are each subdivided by a sliding glass partition into an inner or infant's section and an outer or nurse's section. Each section has its own air intake and exhaust. The nurse enters the

Fig 4—Barrier unit, the partition between nurse's and infant's sections is partly raised.

outer section, prepares there for the care of the infant, raises the sliding glass partition not higher than to her shoulder level, attends the infant and then lowers the partition. A greater air pressure is maintained in the infant's section, so that the flow of air is toward

the nurse's section whenever the partition is raised. The remaining six cubicles are not subdivided.

Clinical observations and bacteriologic investigations were conducted to determine which of the three units was most efficient in controlling the spread of air borne infections.

CLINICAL OBSERVATIONS

The clinical observations were limited to infants in the first three months of life and included only the infections of the respiratory tract, such as the common cold. Therefore, the conclusions could not be applied to older children or to other types of air borne infections, such as chickenpox. Despite these limitations, several distinct advantages offered a unique opportunity for a clinicoepidemiologic study:

1. The three units were completely separated and usually had their own staff of nurses. The number of attendants was about the same in all the units.

2. Except for the special principles under investigation, the conditions in the three units were identical—conditioned air with the same temperature and humidity, equipment, individual aseptic technic and sterile food.

3. The same number of infants of approximately the same age and the same number of premature infants were admitted to all units. The stay was about the same.

4. About the same number of infants and nurses with acute infections of the respiratory tract were admitted to the units.

5. There were no visitors.

6. As hand borne cross infections were practically eliminated at The Cradle, cross infec-

tions of the respiratory tract from infant to infant were considered air borne.

For clinicoepidemiologic information the following routine records were kept: an individual record of each infant, an individual record of each sick nurse and a daily report of the unit. Thus a complete retrospective epidemiologic picture of each unit was maintained.

The number of cross infections of the respiratory tract in infants during the two years before the new nursery was constructed was compared with that for the two years in the new building. There were 68 such infections during the former period and 17 during the latter. The number per hundred infants admitted decreased from 14.5 to 4.6.

The distribution of the 17 cross infections in the three units was striking: 15 in the control unit, 1 in the light unit and 1 in the barrier unit (fig. 5). This distribution was all the more significant because the number of primary infections of the respiratory tract (in nurses on duty and in infants admitted with colds) was about the same in the three units, as shown in the accompanying table.

Fig 5—Distribution of cross infections of respiratory tract in infants in the three units of new building (April 1, 1939 to April 5, 1941): 15 in control unit, 1 in light unit and 1 in barrier unit.

5a Since April 6, 1941, six additional cross infections of infants have occurred in the control unit, none in the two other units.

Ten of the 15 cross infections of the respiratory tract in infants in the control unit occurred during a seasonal outbreak between Feb. 11 and April 5, 1941 (fig. 6). This infection in nurses as well as in infants was characterized by an almost afebrile course, profuse nasal discharge, frequent sneezing, spasmodic cough and, in some infants, pronounced wheezing of several days' duration with sonorous and sibilant rales, mostly during expiration. The spasmodic cough in the first infant was so severe as to lead to the suspicion of pertussis, but laboratory tests including examination of a cough plate did not show *Hemophilus pertussis* or *Hemophilus influenzae*. During this epidemic three infected nurses were on duty in the control unit, six in the light unit and three in the barrier unit. One infant was admitted to the barrier unit with an infection of the respiratory tract. Ten cross infections occurred in the infants in the control unit but none in either the light or the barrier unit. Apparently conditions in the control unit (air conditioning) did not prevent the spread of this respiratory infection, whereas those in the light unit (air conditioning and germicidal light) and in the barrier unit (air conditioning and mechanical barriers) were efficient.

The detailed data compiled during this epidemic shed light on certain epidemiologic questions, such as the

*Distribution of Primary Infections of Respiratory Tract in
Three Units of New Building (April 1, 1939
to April 5, 1941)*

	Control Unit	Light Unit	Barrier Unit

Primary infections of respiratory tract in infants.....	3	1	7
Totals.....	27	28	35

spread and the source of the infection. Figure 6 shows that the spread of the infection was not irregular throughout the unit. At first the infants in about half of the unit showed signs of the infection (infants 1 to 5); then the infection spread to the rest of the unit. Infant 8 was admitted to the cubicle after infant 3 had left. It seemed as if a certain density of the infective agent was necessary to produce the disease and that this density occurred only in the vicinity of the infected infant (see bacteriologic investigations, figure 8).

Detailed data on the source of the infection showed that the infection was introduced into the control unit between February 24 and March 2 by one or two nurses who remained on duty with infections of the respiratory tract (fig. 7). No nurse or infant in this unit had had a cold for three weeks. On March 5 an infant showed the first signs of infection. There followed a period, March 10 to March 17, during which it was impossible to determine whether the transmission occurred from nurse to infant or from infant to infant, because during this period one nurse and 2 infants with infection were in the unit. Although no nurse with symptoms of infection of the respiratory tract was on duty after March 11, the infection continued to spread from March 18 to April 5 until 7 more infants were involved. As several of these infants were severely ill, they were removed from the unit as indicated in figure 7, which shows the duration of stay in the unit. This

period of eighteen days demonstrated clearly that the infection spread from infant to infant. The role of carriers among the nurses was not borne out by our experience at The Cradle, which was that infection of the respiratory tract did not occur in an infant unless

Fig. 6.—Epidemic of infections of respiratory tract (February 11 to April 5, 1941). Chart shows 3 cases of primary and 10 of secondary (cross) infection in the control unit; 6 of primary and 0 of secondary infection in the light unit, and 4 of primary and 0 of secondary infection in the barrier unit.

there was a primary infection in an infant or a nurse. It may be mentioned here that cultures of material from the nose and throat in nurses and infants showed the presence of *Streptococcus hemolyticus* only in the throats of two nurses, one of whom had had repeated colds.

During the two years in the new building there were ninety primary infections of the respiratory tract, seventy-nine among nurses and eleven among infants. In only 5 instances was it evident that a nurse had infected an infant; in 9 instances the transmission occurred from infant to infant; in 3 instances the source of infection could not be determined. As the nurses come in close contact with the infants, it is striking that transmission from nurse to infant was so infrequent. The filtering mask worn by the nurses usually protects the infant.⁶ Recent photographs by Jennison⁷ showed that this mask filtered out droplets.

BACTERIOLOGIC INVESTIGATIONS⁸

Although clinical observations were decisive, bacteriologic tests supplied valuable corroboratory evidence. One of the methods used was to spray a suspension of *Bacillus prodigiosus* in each unit and by means of exposed Petri dishes of culture medium to determine the

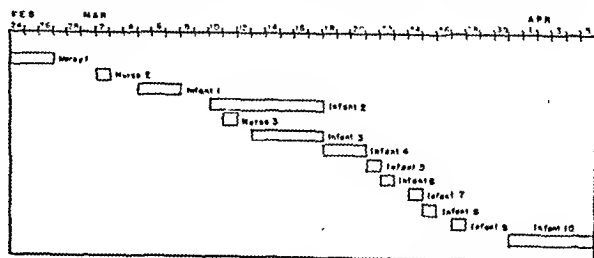

Fig. 7.—Sequence of cases in control unit during epidemic showing the duration of stay of infected nurses and infants in the unit. The infection was introduced by nurses and spread from infant to infant during the last period (March 18 to April 5).

extent of its penetration and survival. This harmless organism was chosen because it lent itself readily to unmistakable identification. It was used in 1926 by

6. McKhann, C. E.; Steeger, A., and Long, A. D.: Hospital Infections, Illinois Health Messenger 10: 38 (March) 1938.

7. Personal communication to the authors.

8. In collaboration with E. Kammerling, B.S., Department of Health, City of Chicago.

Dzialoszinski and Finkelstein.⁹ To simulate the various sites of possible source of infection, the suspension was sprayed in a cubicle in one series of experiments and in the unit corridor in another series. In each experiment plates were exposed throughout the unit. After

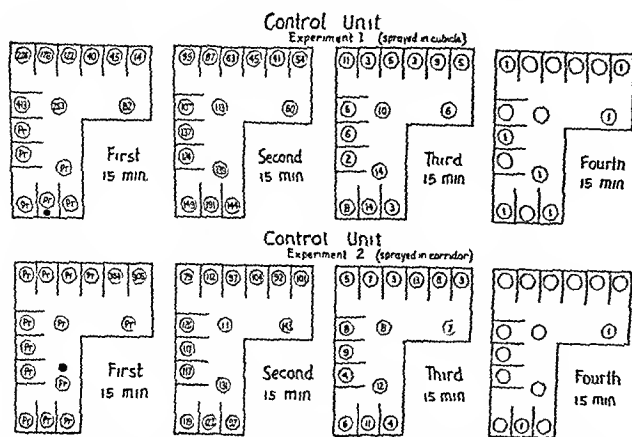

Fig. 8.—Penetration and survival of *B. prodigiosus* in control unit. In experiment 1 a suspension of the organism was sprayed in a cubicle and in experiment 2 in the corridor. The illustration shows penetration into all parts of the unit and the presence of some organisms after forty five minutes. Black dots, site of spraying, numbers in circles, plates exposed and numbers of colonies, Pr, profuse growth.

an incubation period of forty-eight hours at room temperature the number of colonies was counted.

Figure 8 illustrates the findings in two typical experiments in the control unit. In experiment 1 *B. prodigiosus* was sprayed in a cubicle; in experiment 2 it was sprayed in the unit corridor. Plates were exposed for four consecutive fifteen minute periods. In each experiment the colony count demonstrated complete penetration into all parts of the unit. Some organisms were still present forty-five minutes after the spraying. The number of bacteria decreased with the distance from the site of spray.

Similar experiments were conducted in the light unit (fig. 9). It was found that practically no penetration occurred from unit corridor to cubicle or from cubicle to unit corridor. The survival time was limited to the first fifteen minutes, i. e., *B. prodigiosus* was not found on any plate in the unit fifteen minutes after the spraying. These experiments were performed with newly installed lights. Lights in constant use for about four months showed some diminution in germicidal

Fig. 9.—Penetration and survival of *B. prodigiosus* in light unit. In experiment 1 the suspension was sprayed in a cubicle and in experiment 2 in the corridor. There is practically no penetration, and survival is for not more than fifteen minutes.

power. Experiments with the lights off gave results similar to those in the control unit.

Throughout the barrier unit, where doors and partitions had to remain closed during the experiment,

plates were exposed continuously for one hour. Therefore, only the extent of penetration and not the survival could be determined. The results (fig. 10) show that there was no penetration from cubicle to cubicle some from cubicle to unit corridor (as was expected) and but slight penetration from unit corridor to cubicle

COMMENT

These bacteriologic data on the spread of *B. prodigiosus* parallel the clinical observations on spread of infections of the respiratory tract in the three units both over the two year period and during the seasonal epidemic. Fifteen of 17 cross infections of infants occurred in the control unit, where also the seasonal epidemic broke out. *B. prodigiosus*, when sprayed in a cubicle of the control unit, penetrated into all the other cubicles of the unit. When sprayed in a cubicle of the light or the barrier unit this organism did not penetrate into other cubicles of the unit.

During the two years the principle of air conditioning alone, as used in the control unit, did not prevent the spread of infections of the respiratory tract, whereas the addition of germicidal light barriers or mechanical barriers was efficient. Which of the two principles is the one of choice cannot yet be decided. Each has its advantages and disadvantages, several of which may be mentioned. Germicidal light barriers require pro-

Fig. 10.—Penetration of *B. prodigiosus* in barrier unit. In experiment 1 a suspension was sprayed in a cubicle without a partition, in experiment 2 in the infant's section of a cubicle with a partition and in experiment 3 in the corridor. There was no penetration from cubicle to cubicle, slight penetration from cubicle to corridor as was expected, and slight penetration from corridor to cubicle.

tection of nurses and infants to prevent local effects on the skin and the conjunctivas. Investigations on any systemic effects have not yet been made. No harmful effects have been noted. The installation cost of the light is low, but the maintenance cost is high, regular lamp replacements being required. The mechanical barriers have been found somewhat inconvenient by the nurses, because the partitions must be raised and lowered each time an infant is attended. The infant cannot be observed readily. After a few weeks a certain lack of stimulation of the infant is occasionally apparent. On the other hand, the infant is protected against noise, so that the average daily sleeping time is about two hours longer than in the other units. The installation of mechanical barriers is expensive, but the maintenance cost is low. Whether light barriers or mechanical barriers are equally efficient without air conditioning is now under investigation.

CONCLUSIONS

Air conditioning, as used at The Cradle, did not prevent cross infections of the respiratory tract in infants.

Air conditioning and germicidal light barriers or air conditioning and mechanical barriers prevented such infections in infants.

DANGERS OF AERIAL TRANSPORTATION TO PERSONS WITH PNEUMOTHORAX

ROENTGENOGRAPHIC DEMONSTRATION OF THE EFFECT OF DECREASED BAROMETRIC PRESSURE (HIGH ALTITUDE) AND OF INCREASED BAROMETRIC PRESSURE

W. RANDOLPH LOVELACE II, M.D.
Major, M. C. U. S. Army; Assistant Air Surgeon
ANDH. CORWIN HINSHAW, M.D.
ROCHESTER, MINN.

Free gas within the human body tends to increase in volume when a person ascends in altitude and to decrease in volume when the atmospheric pressure is increased. This is in accordance with Boyle's law, which states that the volume occupied by a given quantity of gas is inversely proportional to the absolute pressure exerted on it (figs. 1, 2 and 3). Gas enclosed within a body cavity is under pressure of the external atmosphere, but this pressure can be modified significantly by the elastic properties of the walls of the enclosing organ and by pressure of surrounding structures. Those body cavities which communicate with the external atmosphere, such as the paranasal sinuses, are capable of equalizing pressure changes, provided the ostiums are not obstructed, but such equilization is not possible within the cavity of a closed pneumothorax. These changes occur at comparatively low altitudes; for example, 1,000 cc. of air (saturated with water vapor at 37 C.) becomes 1,500 cc. of air at the moderate altitude of 10,000 feet above sea level, since the volume of gas thus enclosed in the body tends to vary in volume according to the ratio $\frac{760-47}{\text{Bar}-47}$. It must be noted that air within body cavities is saturated with water vapor and that the pressure of water vapor at 37 C. is 47 mm. of mercury. This ratio omits the small factor of negative intrapleural pressure, which amounts to only a few millimeters. It is obvious that the higher the altitude reached, the greater is the effect of water vapor (fig. 1).

Pneumothorax is of particular interest to the physician who deals with problems of aviation medicine. Under no other conditions is such a large quantity of gas enclosed within the body cavities with no means of escape. This large quantity of gas is enclosed by tissues which are usually elastic, offering little resistance to expansion. The adjacent organs are of extreme physiologic importance, and their functions may be seriously impaired if they are much compressed. Phthisiologists have learned that it is essential that artificial pneumothorax be maintained under as uniform a pressure as is practicable and that great caution be exercised to avoid either excessive reexpansion of the lung or excessive compression of the lung in refilling the pneumothorax cavity. Rapid and frequent and decided contraction and expansion of the collapsed lung might well be deleterious to the healing process. These precautions are necessary to prevent mechanical forces from interfering with the healing of tuberculous lesions by fibrosis and to prevent the rupture of pleural adhesions, which so frequently are present. Adhesions frequently are attached to diseased lung tissue and when torn loose may result in a seeding of the pneumothorax cavity with *Mycobacterium tuberculosis* and

the production of pleuritis, which may obliterate a valuable pneumothorax space or even lead to tuberculous empyema. Excessive compression of the lung also may reduce the vital capacity seriously and produce displacement of mediastinal structures with uncomfortable or even serious results. If expansion of the gas within the cavity does not occur, even greater strain might be placed on intrathoracic structures.

Further study of the effect of altitude on pneumothorax is especially timely because of the rapidly increasing use of the airplane as a means of long distance transportation.¹ The number of persons for whom artificial pneumothorax has been carried out is steadily increasing as a result of the increasing favor of this method of treating pulmonary tuberculosis. In a large majority of cases of active pulmonary tuberculosis, treatment by artificial pneumothorax is the treatment of choice. When satisfactory collapse is obtainable symptoms are promptly controlled, and as long as the state of collapse is maintained lesions usually remain latent. It has not been possible to determine when pneumothorax may be discontinued with safety; hence many physicians are recommending that pneumothorax be continued for several years and sometimes for many years, even though the patient remains well and an active member of society. As a result there are now thousands of persons with pneumothorax and many of them will be so maintained for years, if not for their entire lifetime. Furthermore, traumatic pneumothorax is not uncommon in injuries to the thorax, and spontaneous pneumothorax occasionally develops. For these reasons we believe it to be extremely important that physicians and patients learn all that can be known of the physiologic and pathologic effects of flight on the patient with pneumothorax.

In 1940 Gellenthien,² in an article on altitude and artificial pneumothorax, pointed out that a factor which may upset the equilibrium of a perfect collapse and be dangerous to the patient is the change in atmospheric pressure resulting from decided changes in altitude in traveling either by air or by surface transportation in mountainous regions. A formula was given to determine how high a person with a pneumothorax can go without the occurrence of positive pressure after a fresh supply of air has been injected into the pleural cavity. One of us³ in 1940 pointed out the effect of decreased barometric pressure on the volume of gas in a closed pneumothorax.

It is immediately obvious that clinical and physiologic studies should be conducted among patients with pneumothorax to determine, if possible, how closely the theoretical hazards and the practical hazards of airplane travel coincide. Clinical experience has taught that many patients with artificial pneumothorax may fly as passengers in commercial airplanes and suffer no immediate ill effects. Complaints have been so few that most physicians have not warned such patients to avoid flying. It is certain that these physicians would be most alarmed should an artificial pneumothorax be refilled with 1,000 cc. of air or more; yet this is precisely what should happen, theoretically, when a patient with a large pneumothorax cavity ascends to the moderate altitudes frequently attained by commercial planes.

3. Lovelace, W. R., II, in discussion, *J. Aviation Med.* 11:9-11 (March) 1940.

In 1929 Rabino⁴ reported a case in which discomfort during aerial flight occurred in a patient with artificial pneumothorax. In the same year Margaria, Talenti and Reviglio⁵ reported their results of experiments on animals and advised against the aerial transportation of patients with artificial pneumothorax.

It would appear to be extremely important to determine by accurate roentgenographic methods whether or not the calculated expansion of pneumothorax during flight actually occurs or whether expansion is restrained and relative positive pressure develops. The theoretical degree of expansion which occurs at high altitude and an analysis of the several factors contributing to it have been published by Gellenthien and were discussed by one of us (Lovelace) in 1940.

Verification of these theoretical effects could not be conveniently accomplished during actual flight because of technical roentgenologic difficulties, but it is possible

thorax to expand on the basis of thickened pleura, adhesions, small capacity or other mechanical factors. One such patient underwent external pressures varying from two atmospheres to a half atmosphere with no visible differences in the roentgenograms. In this instance the condition of artificial pneumothorax was

Fig. 1.—Comparative volumes of gases (saturated at 37 C.) inside the body at various altitudes. The pressure of water vapor at 37 C. (98.6 F.) equals 47 mm. of mercury.

to simulate any desired altitude within a low pressure chamber which is capable of accommodating the patient and the necessary apparatus. We have carried out this procedure in the Mayo Clinic Laboratory for Research in Aviation Medicine (Dr. Walter M. Boothby, director) and have been able to obtain roentgenograms of the thorax of good technical quality which clearly reveal the changes which occur in the size of a pneumothorax cavity when the pressure of the external atmosphere is either increased or decreased.

As anticipated, there was considerable variation among different patients. A few were found whose pneumothorax did not expand to the degree anticipated by the application of Boyle's law. In these instances it was possible to explain the failure of the pneumo-

Fig. 2.—Comparative volumes of gases (saturated at 37 C.) inside the body at various increased and decreased barometric pressures

being discontinued, and the negative pressure doubtless was unusually high. The patient had recently suffered from severe pleuritis, and a considerable degree of pleural thickening was visible in the roentgenograms of the thorax. This patient experienced no subjective symptoms during the study, but the intrapleural pressures must have varied widely in relation to the other thoracic structures.

Another patient was studied for whom extensive basal pneumothorax had been established and who had been receiving frequent large "refills" under positive pressure by his home physician, with the production of a posterior basal mediastinal hernia and considerable dyspnea and thoracic discomfort. In figure 4a is shown the appearance of this particular pneumothorax at Rochester (elevation 1,000 feet above sea level) and in figure 4b is depicted the effect resulting from pressure of two atmospheres (1,525 mm. of mercury). These figures demonstrate that the pneumothorax cavity was reduced to approximately half its former size, with consequent reexpansion of the lung and relief of

Fig. 3.—Comparative volumes of gases (saturated at 37 C.) inside the body at various increased atmospheric pressures

the patient's dyspnea as long as the external pressure was maintained (figs. 2 and 3). By this method it was possible to visualize roentgenographically how the pneumothorax, the lung and the mediastinum would appear when the pneumothorax was reduced in volume by a half, and this was accomplished without entering the pneumothorax cavity and within a few minutes time.

4 Rabino, A.: Pericoli dei viaggi aerei durante la cura pneumotoracica, *Minerva med.* (pt. 1) 9: 624-626 (April 28) 1929.
5 Margaria, R.; Talenti, C., and Reviglio, G. M.: Modificazioni indotte dalla depressione barometrica sul pneumotorace: Studio sperimentale radiologico, *Minerva med.* (pt. 2) 9: 637-647 (Oct. 27) 1929.

Three other patients entered the low pressure chamber, and the external pressure was reduced to simulate the effect of altitude of from 8,000 to 12,000 feet. Two of these patients had experienced discomfort during flight, and the procedure reproduced these symptoms. In 1 of these patients severe pleuritic pain in the anterior part of the thorax had developed on his ascent in a commercial passenger airplane to an altitude of 9,000 feet. He had sought medical advice as to the safety of this form of transportation in the future. The conditions of this flight were simulated in a low pressure chamber. The extent of the pneumothorax at ground level (1,000 feet), with extensive adhesions between the lung and the thoracic wall which appeared to be adequate to account for his pain, is shown in figure 5 *a*. The effect of simulated ascent to 10,000 feet is shown in figure 5 *b*. The effect on the small circumscribed basal pocket containing some fluid is especially apparent.

Another instance illustrating the effect of altitude on a pneumothorax is shown in figure 6 *a* and *b*. The appearance at ground level (1,000 feet) is shown in figure 6 *a*, and the effect of a simulated ascent to 10,000 feet is shown in figure 6 *b*. This patient had flown frequently and it was strongly suspected that the pleural

at low altitudes may give a patient a false impression of safety, encouraging him to engage in further flight in which higher altitudes are reached, because of weather conditions or because of the duration of the flight, with discomfort or actual danger to the patient. The evidence accumulated seems adequate to justify warning all

Fig. 5.—Partial artificial pneumothorax: *a*, appearance at Rochester ground level; *b*, appearance at simulated altitude of 10,000 feet above sea level. Compare size of basal fluid containing air pocket and of large apical pneumothorax with that in figure 5 *a*.

Fig. 4.—Basal pneumothorax and mediastinal hernia to contralateral side: *a*, appearance of the thorax at Rochester ground level (1,000 feet above sea level); *b*, appearance when atmospheric pressure is increased to twice that of sea level.

effusion was the result of the frequent, rapid and decided changes in the degree of collapse. The degree of collapse produced in the low pressure chamber was very similar to that which would be anticipated by the application of Boyle's law. It is important to emphasize the fact that great changes in pneumothorax volume were observed in these studies, with little or no subjective discomfort for 2 of the patients. Such large changes in volume would appear to be very hazardous, but the patient's subjective symptoms would not always give warning of these apparent hazards. When symptoms did appear, they were apparently attributed to traction exerted on pleural adhesions or to reduction in vital capacity as a result of excessive collapse. Willcox and Foster-Carter⁶ reported a case in which spontaneous pneumothorax occurred, during flight, in a pilot who had associated bullous emphysema as proved by roentgenograms and necropsy.

It would appear to be impossible to predict the safe "ceiling" for any patient with pneumothorax without actually subjecting him to flight or to experiments within a low pressure chamber, including the making of serial roentgenograms. Previous experience in flight

patients with pneumothorax to avoid transportation by airplane unless they can be assured that no altitude will be attained beyond that which they have previously tolerated without discomfort. Even under the latter condition it is possible that some harm might be done to unstable tuberculous lesions by the rather large degrees of alternate expansion and collapse which may be occurring repeatedly during a flight, especially when there are frequent landings. Traumatic or spontaneous pneumothorax would be affected in a manner similar to that described for artificial pneumothorax.

It should be reemphasized at this time that transportation by airplane offers no such hazards for those who do not possess pneumothorax, and that the exceptional comfort and speed available in modern airplanes, as well as care by stewardesses who are registered nurses, make airplane travel an ideal method of transportation for most patients. We believe, as a matter of fact, that physicians should encourage their patients to use the air-

Fig. 6.—Hydropneumothorax: *a*, appearance at Rochester ground level; *b*, appearance at simulated altitude of 10,000 feet.

plane as a preferred mode of transportation. It is definitely superior to the automobile if the distance involved is considerable.

SUMMARY

Roentgenographic studies of the effects of increased and decreased barometric pressure on pneumothorax have been made. It has been possible to demonstrate

⁶ Willcox, A., and Foster-Carter, A. F.: Spontaneous Pneumothorax Associated with Bullous Emphysema, *Lancet* 2:315-317 (Aug. 7) 1937.

that the principle of Boyle's law applies to closed free pneumothorax. The degree of increased pulmonary collapse produced by a simulated increase in altitude, however, may be restricted by pleural adhesions, by thickening of the visceral pleura and by fixation of the mediastinum. The moderate altitudes (5,000 to 12,000 feet) commonly attained by commercial passenger carrying airplanes are sufficient to produce a pronounced increase in the size or the pressure of a pneumothorax, whether this is of therapeutic, spontaneous or traumatic origin. The dangers attending fluctuations in degree of pulmonary collapse are increased shortly after "refilling" of a pneumothorax, when pleural adhesions are present, when disease in the collapsed lung recently has been active, when the patient's vital capacity is limited or when the pneumothorax is unusually extensive. Patients with a pneumothorax created for therapeutic reasons should be warned of these dangers, and physicians who care for injured persons should recall the possibility that traumatic pneumothorax might be present, presenting similar hazards if the patient is transported by airplane.

HEPATIC CHANGES PRODUCED BY ESTRONE, ESTRADIOL AND DIETHYLSTILBESTROL

CYRIL M. MACBRYDE, M.D.

AND

OLGA BIERBAUM, B.S.

ST. LOUIS

In a previous communication we¹ showed that both diethylstilbestrol and estradiol may produce profound changes in the bone marrow and peripheral blood of dogs. The doses of these estrogens were in excess of the therapeutic range used in man. Changes in the liver consisting of fatty degeneration and central necrosis also were observed following the use of both drugs. However, these changes were not consistent and at the time we were unable to determine whether the hepatic change was the result of direct damage to the liver by the drugs or whether the hepatic damage was secondary to the changes in the bone marrow and peripheral blood.

Extensive clinical studies have resulted in a variance of opinion among different groups regarding the toxicity of diethylstilbestrol. Although some workers have suggested that side actions such as nausea may be the result of hepatic damage, no direct proof of this has been determined. One report implies that histopathologic hepatic changes may have been produced in a patient as the result of the administration of diethylstilbestrol.² Davis,³ in 5 cases in which large doses of diethylstilbestrol were administered, found no histologic hepatic change which he felt could be attributed to the drug. Our studies indicate that any liver change occurring in dogs receiving diethylstilbestrol may also

be found as the result of the administration of estrone or estradiol. It should be emphasized that microscopic studies of the livers of patients who have received large doses of the so-called natural estrogens are as yet wholly lacking. Apparently the "natural" or animal origin of these estrogens has not led to the suspicion that they might produce hepatic damage, while the synthetic nature of diethylstilbestrol immediately led to such suspicion.

PLAN OF STUDY

It seemed desirable to ascertain by a parallel study the effect on the livers of dogs of the more commonly used natural estrogens estrone and estradiol and of the synthetic estrogen diethylstilbestrol when administered in estrogenically equivalent doses.

As has been previously shown, natural or synthetic estrogens when administered to dogs produce profound changes in the blood and bone marrow. With progression of these changes, thrombocytopenic purpura occurs, which is followed by severe anemia and cachexia. It seemed possible that the anemic and the cachectic states might of themselves produce hepatic damage or might enhance previously existing hepatic damage and thereby interfere with the interpretation of the changes which might be produced in the liver by the estrogenic substances. In the present study, to avoid these possible complicating factors in the interpretation of the changes in the liver, we killed the animals before hemorrhage occurred.

MATERIALS AND METHODS

Eleven healthy dogs were used, 6 males and 5 females. All the animals were kept in the animal quarters for approximately two weeks before the studies were begun. In addition 4 dogs, 3 males and 1 female, served as controls and were examined post mortem at the end of the conditioning period. During this period of adjustment, red, white, differential, reticulocyte and platelet counts were done on the peripheral blood. After the experiments were started the peripheral blood elements were studied at frequent intervals.

The estrogens used were estrone, estradiol benzoate and diethylstilbestrol dipropionate.⁴ These substances were administered daily by intramuscular injection. Crystalline diethylstilbestrol dipropionate was also given by mouth.

In order that comparative observations might be made, the estrogenic potency of the estrone, estradiol benzoate and diethylstilbestrol dipropionate was calculated in terms of international units. Because of the diverse nature of these estrogens and the different methods of assay used in estimation of their potency, comparisons can of necessity be only approximate. One mg. of estrone is equivalent to 10,000 international units. Estradiol benzoate has a potency of 6,000 rat units per milligram. One mg. of diethylstilbestrol dipropionate is equivalent to 20,000 international (estrone) units. It is widely accepted that 1 rat unit is approximately equivalent to 10 international units. Therefore 5 mg. of diethylstilbestrol dipropionate is calculated to have roughly the same estrogenic potency as 1.66 mg. of estradiol benzoate or 10 mg. of estrone (100,000 international units). It must also be remembered that the esterification of estrogens as the dipropionate or the benzoate also influences the comparison of the endocrine activity, both as to potency and as to duration of action.

⁵ 3. Davis, M. E.: A Clinical Study of Stilbestrol, *Am. J. Obst. & Gynec.* 39: 938-953 (June) 1940.

⁴ 4. Estrone for these studies was supplied by Roche-Organon, Inc., Nutley, N. J. Estradiol benzoate was supplied by the Medical Research Division of Schering Corporation, Bloomfield, N. J. Diethylstilbestrol was furnished by the Department of Medical Research of the Winthrop Chemical Company, New York.

Three dogs each received 100,000 international units of estrone (10 mg.) daily by injection. A group of 3 dogs were each given 10,000 rat units (1.66 mg.) of estradiol benzoate daily by injection. Diethylstilbestrol dipropionate was given to each of 3 dogs by daily injection in doses of 5 mg. (approximately 100,000 international units). Thus each dog in each of the three groups was given a daily dose of the respective estrogen approximately equivalent to 100,000 international (estrone) units.

One male and 1 female dog were given 400,000 international units (20 mg.) of crystalline diethylstilbestrol daily by mouth. This dose is four times that given by injection and is not calculated to be comparable in estrogenic potency to the estrogens given by injection.

All animals were killed when a severe thrombocytopenia developed but before the purpuric and hemorrhagic states occurred. Portions of liver and bone marrow from selected sites were immediately fixed in Bouin's solution. In addition, portions of liver were fixed in absolute alcohol and examined for glycogen by Best's carmine stain and in solution of formaldehyde U. S. P. diluted 1:10 and examined for fat by the scarlet red and Nile blue sulfate stains.

RESULTS

Liver.—The changes produced in the livers of the dogs receiving the different types of estrogenic substances were essentially similar. These alterations varied among the groups of dogs receiving different estrogenic substances, but this variation was no more pronounced than in a single group of dogs receiving the same estrogenic substance. In general the changes occurring in the parenchymal cells of the liver were not prominent.

Of the 3 dogs receiving diethylstilbestrol by injection, 1 showed slight to moderate fatty degeneration confined chiefly to the middle zones of the liver lobules and slight shrinkage of the hepatic cells centrally. The

Fig. 1 (dog 19).—No drug given. Normal liver. The cytoplasm is rich in glycogen. In all four photomicrographs the stain was hematoxylin and eosin, and all are slightly reduced from a magnification of 133 diameters.

livers of the other 2 dogs exhibited slight fatty and hydropic degeneration of the hepatic cells confined chiefly to the central zones but not involving all central zones.

Of the 3 dogs receiving estradiol benzoate by injection, 1 showed moderate to advanced fatty and hydropic degeneration of the hepatic cells centrally and a slight

fatty degeneration of the other hepatic cells. There was moderate intracellular and extracellular hemosiderin in fine granules present in the central zones. There were a few polymorphonuclear leukocytes present in the central zones, but no fibrin was identified. The hepatic changes in the other 2 dogs consisted of slight

Fig. 2 (dog 30).—Diethylstilbestrol. Minimal fatty degeneration, predominantly central. Myelopoiesis about central vein.

shrinkage of the cells centrally and in some instances mild fatty and hydropic degeneration of the cells in the central zones.

Of the 3 dogs receiving estrone, 1 exhibited advanced fatty and hydropic degeneration of the hepatic cells centrally together with loss of nuclei and cell outlines in some instances. There was no noticeable infiltration of polymorphonuclear leukocytes within the vacuolated areas, although many of the zones contained foci of myelopoiesis. The hepatic changes in the remaining 2 dogs consisted of slight shrinkage of the central cells in some instances and occasionally slight fatty degeneration of the hepatic cells.

Of the 2 dogs receiving diethylstilbestrol by mouth, the liver of 1 showed a minimal amount of central fatty degeneration and slight shrinkage of cells centrally. The liver of the other dog showed a minimal amount of fatty degeneration diffusely distributed throughout the lobules.

The amount of fat present within the livers as determined by the scarlet red and Nile blue sulfate stains was at times no more pronounced in those animals receiving the various types of estrogen than it was in normal animals.

In several specimens the vacuoles within the hepatic cells failed to stain with scarlet red but took a blue or purple tint with the Nile blue sulfate stain. In a few specimens the hepatic cells centrally contained vacuoles which failed to stain with either the scarlet red or the Nile blue sulfate stain and were considered to be hydropic degeneration.

The amount of glycogen present within the livers as determined by Best's carmine stain showed considerable variation but was usually scanty. In no instance could glycogen be demonstrated in the large clear vacuoles. No correlation could be established between the amount of glycogen present and the degree of fatty and hydropic degeneration. Our observations are therefore at variance with those of Teague,⁵ who studied

5. Teague, R. S.—The Effect of Estrogens on the Microscopic Appearance of the Liver. *J. A. M. A.* 117:1242-1243 (Oct. 11) 1941.

the effects of diethylstilbestrol and of estradiol on the livers of rats. He concluded that the vacuolization of the liver cells was due to accumulation of glycogen rather than to hydropic or fatty degeneration.

One of the most striking findings in the liver was the occurrence of foci of myeloid cells about the central veins and occasionally about the portal spaces. These cells varied from predominantly immature myeloid cells to predominantly mature polymorphonuclear leukocytes. In those animals in which the hyperplasia of the bone marrow was least pronounced the liver usually contained fewer and smaller foci of myeloid cells. In those animals in which myeloid foci were present in the liver the degree of maturation of the myeloid cells in the liver tended to parallel the degree of maturation of myeloid cells in the bone marrow. An occasional mitotic figure was encountered in the foci of myeloid cells in the liver.

Bone Marrow.—Examination of the bone marrow from the vertebrae, ribs and long bones revealed an alteration of the normal marrow elements. This alteration showed slight quantitative variations but was otherwise essentially similar in all instances, regardless of the type of estrogen used. In general, regardless of the type of estrogenic substance employed, the marrow showed a variable degree of hyperplasia, predominantly of the myeloid elements. However, the state of maturation of the myeloid cells was variable, some marrows showing predominantly immature cells, some showing predominantly mature polymorphonuclear leukocytes and others showing focal areas composed chiefly of either immature or mature cells. The degree of maturation was usually more advanced in marrows studied from the long bones and ribs than it was in marrow selected from the vertebrae. In many instances the erythrogenic elements were obscured by the myeloid hyperplasia, but in general erythropoiesis appeared reduced. In a few specimens there were scattered small foci of hypoplasia in which the erythrogenic cells predominated. The stroma within these foci was loose and

was not a striking feature. Other megakaryocytes contained only two to three nuclei.

Peripheral Blood.—Essentially the same response was produced in the peripheral blood elements by estrone and estradiol benzoate as was observed with diethylstilbestrol dipropionate. The changes produced by the

Fig. 4. (dog 39).—Estrone. Slight central fatty degeneration. Myelopoiesis about central vein.

various estrogens were indistinguishable as to quality and degree. The findings in each group consisted of leukocytosis and an almost simultaneous rapid fall in the thrombocytes. In some instances the platelets disappeared entirely from the blood. A moderate decrease in the red blood cells and hemoglobin was observed to follow the rise in granulocytes. The decrease in red blood cells and hemoglobin took place in the absence of hemorrhage, the occurrence of which we were careful to avert. These animals were not allowed to run their full course, since in this study we were primarily interested in hepatic changes. A full report of hematologic observations has been published.¹

COMMENT

Until comparatively recently it was believed that all estrogenic substances must contain the phenanthrene nucleus. It is now known that many synthetic compounds not containing the phenanthrene nucleus are estrogenic. Diethylstilbestrol, the most widely studied of the synthetic estrogens, is approximately twice as potent when injected intramuscularly as the natural hormone, estrone. Even more important from the clinical standpoint is the fact that, unlike the natural estrogens, it is highly effective when taken orally. Since diethylstilbestrol does not occur in the animal body, it must be considered a drug rather than a hormone. For this reason a great deal of attention has been devoted to its possible toxic effects. Studies of hepatic function performed by ten different groups of workers on a large number of patients have not shown any clearcut evidence of damage to this organ.⁶

The fact that several investigators⁷ have found evidence of hepatic damage resulting from the administration of diethylstilbestrol when given in very large doses

Fig. 3 (dog 24).—Estradiol benzoate. Minimal central hydropic and fatty degeneration. Myelopoiesis about central vein.

edematous and frequently took a faintly basophilic or acidophilic stain. One of the most constant changes throughout all the specimens of marrow studied was a sharp decrease in the number of megakaryocytes. In many instances several microscopic low power fields failed to disclose a single megakaryocyte. Occasionally these cells showed shrunken basophilic nuclei, but this

7. Loeser, A. *Klin. Wchnschr.* 18: 346, 1939. Grunke, P. *ibid.* 18: 1195, 1939. Sebe, H. *ibid.* 18: 1195, 1939. von Haam, E. *ibid.* 18: 1195, 1939. Rardin, T. E., and Schene, R. *ibid.* 18: 1195, 1939.

to animals indicates the need for a study such as the one presented here. The synthetic nature of diethylstilbestrol has no doubt caused the concentration of toxicity studies on it. Heretofore the possible toxic effects of the so-called natural estrogens have been neglected. We therefore have given approximately equivalent estrogenic doses of the natural hormones and of diethylstilbestrol to dogs and have studied the effects. The results of the present study confirm our previous observations¹ that diethylstilbestrol and estradiol produce similar effects on the blood and bone marrow of dogs. We have in addition, as shown in the table, found

observation or tests of hepatic function any evidence of damage to the liver among a large number of patients treated with diethylstilbestrol. It seems unlikely that the usual therapeutic doses of diethylstilbestrol or of the natural estrogens will produce hepatic damage. There may, of course, be a great difference in species susceptibility, but it would seem possible that extremely large doses of either synthetic or natural estrogens might produce changes in the liver in human beings. We may conclude from this study that, when given to dogs, large doses of the natural estrogens estrone and

that estrone produces results indistinguishable in these respects from those following estradiol or diethylstilbestrol. The livers of animals receiving large doses of estrone or of estradiol benzoate showed definite changes which cannot be distinguished in type or degree from the hepatic changes produced by estrogenically equivalent doses of diethylstilbestrol dipropionate.

It must be emphasized that the doses of the estrogens used in these experiments are approximately twenty-five times as large per unit of body weight as the maximum therapeutic dose usually employed in treating patients. We have not been able to detect by clinical

estradiol produce hepatic changes indistinguishable from those produced by diethylstilbestrol.

SUMMARY

Large doses of the "natural" estrogens estrone and estradiol benzoate produce changes in the liver, bone marrow and peripheral blood of dogs indistinguishable from those produced by the synthetic estrogen diethylstilbestrol. Hepatic changes following estrogenically equivalent doses of the three estrogens consisted of fatty degeneration and hydropic degeneration. In general, alterations in the parenchymal cells were not widespread or prominent. Since these changes occurred before the appearance of any hemorrhagic state, they were presumably the result of direct action on the liver. Extramedullary myelopoiesis occurred within the livers of animals receiving these estrogens.

VERTIGO DUE TO OBSTRUCTION OF THE EUSTACHIAN TUBES

A CLINICAL STUDY BASED ON ONE HUNDRED AND THIRTY-FIVE CASES

F. W. MERICA, M.D.

LAKEWOOD, OHIO

Vertigo caused by obstruction of the eustachian tubes is a distinct clinical entity which has received but scant attention both in the literature and in practice. My own experience in the treatment of 135 cases of this type has proved that many patients suffer unnecessarily the distressing symptoms of vertigo, nausea and vomiting, sometimes for long periods, because their physicians fail to recognize the cause and to institute the simple procedure of mechanical inflation of the eustachian tubes which would bring them relief.

The reason these cases are so consistently overlooked probably is that they are seen usually by the medical man or general practitioner, who is likely to think in terms of disturbances in the digestive, circulatory or nervous systems and hence to ignore the possibility that violent symptoms of dizziness, nausea and vomiting may be attributable to stenosis of the eustachian tubes.

Most of the references to vertigo of this type in the literature have been made in general discussions on vertigo due to various causes, but a number of authors, including Atkinson,¹ Baumel,² Brand,³ Scott,⁴ Mollison⁵ and Richey,⁶ have listed eustachian obstruction or stenosis as one of the principal causes of vertigo. It is true, of course, that there are many other conditions which may cause vertigo, but since obstruction of the eustachian tube is one of the most obvious, and also the most easily corrected, every patient with symptoms of dizziness and nausea should be subjected to the therapeutic test of inflation of the tubes as a first step in a thorough clinical investigation. This procedure should be carried out only by an otolaryngologist who is skilled in the passing of eustachian catheters and bougies.

GENERAL CONSIDERATIONS

My records of the past few years include 135 cases of vertigo relieved by inflation of the eustachian tubes. In this series of patients 34 per cent were men and 66 per cent were women. Approximately half of the group were between 40 and 60 years of age. Eighty per cent were between 30 and 70, and the remaining 20 per cent were young or extremely aged.

The obstruction or stenosis of the eustachian tubes was associated with acute or chronic inflammation of the nasal sinuses or ears in a large proportion of cases. The condition was associated with head colds in 15 instances. Fifteen patients complained of a feeling of fullness in the ears, along with the vertigo. Tinnitus accompanied the vertigo in 53 instances, and 39 patients had some reduction of hearing. In 7 of these the dis-

turbance in hearing was temporary. Only 2 patients had discharging ears. Tonsillitis was present in 2 cases. One case was associated with alcoholism.

The duration of the vertigo was variable. In some cases the symptoms had been present only a few days; in others, weeks, months and even years.

SYMPTOMS

Many of the patients in this series had been under treatment for long periods and had gone to numerous physicians to seek relief from nausea, poor appetite, so-called bilious attacks, constipation, nervousness and many other symptoms, which usually had been ascribed to digestive disturbances. I have seen 2 or 3 patients who had histories quite typical of peptic ulcer and had been under observation and treatment for this condition, with no relief. Later their distressing symptoms were completely controlled by reestablishment of the patency of the eustachian tubes.

The cases of insidious onset are the ones most likely to be overlooked. In these instances, because the gastrointestinal symptoms are predominant, the patients are likely to be subjected to various types of treatment over long periods for diseases of the digestive system.

When the onset of the symptoms of nausea and vertigo is sudden and severe, the diagnosis is more easily established, and, if the proper treatment is instituted promptly, the relief is striking and dramatic.

A typical instance in which the onset was sudden was that of a young physician, previously in good health, who was extremely dizzy and severely nauseated one morning as he attempted to get out of bed. He lay back in bed and found that every time he moved or tried to raise his head he was overcome by extreme nausea to the point of vomiting. He became alarmed about his condition and called Dr. James T. Ledman, who recognized the trouble and suggested that he come to my office for treatment. (Dr. Ledman is an internist who has frequently made the diagnosis in this series and has referred the patients to me for treatment.)

Because the patient was suffering from such extreme nausea, it was 12:30 before he could get to my office. He came in, assisted by his wife, carrying a large towel and an emesis basin. He was walking with his legs far apart and holding on to the wall. He was extremely pale and was perspiring profusely. After he was assisted to the chair, a catheter was passed into the eustachian tubes; this was followed by a bougie, and then slight air inflation. Only the right eustachian tube was obstructed, and when this was opened the patient moved his head from side to side and stared in amazement as he announced "Why, my dizziness is gone!" He rose from the chair immediately, stood up, turned a few times, and walked around the room, shaking his head from side to side, and still could elicit no vertigo. Then he said suddenly "I have a call to make at 12:30—I can still get there." And he rushed from the room.

There have been many other instances just as dramatic as this one. In fact, the physician who was the patient in the foregoing instance was responsible for referring the following patient, and this shows that the results can be just as striking when the symptoms have been present for a long period.

The patient was a man past 60 who had a moderate hypertension. He had been confined to his bed for six weeks because of vertigo and had difficulty at times

in retaining his food, because the effort of trying to sit up and eat frequently caused severe vomiting. Hence his physician asked me to go to his home, to carry out the treatment. A eustachian catheter, and then a bougie were passed, and the middle ear was inflated with a hand bulb. The right tube was patent, but the left was closed, and after it was opened the patient raised his head and said "My dizziness is gone!" Whereupon he got out of bed and walked around the room unassisted. This occurred three months ago, and the patient has had no recurrence of the dizziness since.

In some cases the onset of symptoms is fleeting. The patient may awake some morning and, in attempting to turn over in bed, notice a transitory dizziness. If he attempts to get out of bed suddenly, an attack of severe vertigo may ensue, so that he may have to steady himself or be assisted to keep from falling. Frequently in such instances, if the patient gets to his feet and stands still for a few moments with his eyes closed, the dizziness disappears, and then, with some care, he is able to go about his daily routine. Sudden change of position, such as stooping, however, may bring on the vertigo for several minutes. As the day goes on, the symptoms become less pronounced and the patient may be comparatively free from trouble during the day. For this reason a patient with this type of history does not seek relief until the condition becomes worse and he is incapacitated by it.

RECURRENCES

Although some patients in this series have apparently received permanent relief from only one inflation of the eustachian tubes, there have been many who had a recurrence of the same symptoms, which were again relieved by inflation of the eustachian tube. These recurrent attacks may be associated with acute head colds or exacerbations of a catarrhal condition or some irritation of the mucous membranes such as that caused by excessive smoking.

In some cases, in which the condition has progressed gradually over a long period, dilation of the eustachian tubes at regular intervals has proved necessary. Some patients have been treated regularly for two years or more. As an example, I have in mind a patient who was past 70 years of age. For a time he came in at regular intervals and was thus able to carry on his business and go to his office routinely. However, if he lapsed in his routine of treatment he would wake up a few mornings later to find that he was unable to get out of bed and would start vomiting severely. On several occasions it was necessary for me to go to his home to carry out the treatment. I have been called to his home and found him in a darkened room, flat on his back with ice cloths over his eyes, and any movement or attempt to talk would bring on severe retching. Yet after treatment he would be out of bed, dressed and on his way to his office within half an hour.

TREATMENT

As already indicated, the treatment consists in passing a catheter into the eustachian tube and then a bougie, followed by inflation with air. When this procedure is carried out with care and caution there is no danger of rupture of the tympanic membrane or trauma to the eustachian tubes. I have used the procedure thousands of times without ill effects of any kind.

Although the immediate aim in these cases is to establish the patency of the eustachian tube at once—

and this must be done by the mechanical procedure outlined—it is also important to maintain the patency of the tube. In some cases this can be achieved only by repeated inflations, but in others a thorough investigation may reveal some underlying difficulty that can be corrected. Chronic sinus infections, chronic tonsillitis and ear infections may be causing or contributing to the obstruction of the eustachian tubes, and, if present, the proper measures should be taken to eradicate them.

Allergy is a factor in some of these cases, and the patency of the eustachian tubes can be maintained by removal of the offending allergen. As has been noted, 1 case in the series was associated with alcoholism. Many patients have experienced great improvement by moderation or elimination of smoking. Abstinence from tobacco is always advisable in these cases.

It is also worth while to investigate the basal metabolic rate of patients with recurrent vertigo due to eustachian obstruction. A significant number have a low metabolic rate, and the patency of the eustachian tubes is improved or maintained when thyroid is administered.

COMMENT

Although my purpose in this presentation is to discuss the clinical manifestations and treatment of obstruction of the eustachian tubes, a word may be added concerning the probable mechanism by which the symptoms are produced. It seems obvious that obstruction of the eustachian tube somehow disturbs the air pressure and causes stimulation of the perilymph, which interferes with normal balance as maintained by the labyrinthine mechanism.

Vertigo is caused in most cases, and perhaps in all, by unilateral eustachian obstruction. The obstruction was recorded as bilateral in approximately one third of the cases I have observed, but it may be that the pressure disturbance in these cases was unequal on the two sides. In another third of the cases the obstruction was unilateral, and in the remaining third one side was more completely obstructed, or the obstruction occurred on alternate sides in different attacks and hence could be regarded as unilateral. Scott¹ noted in the examination of aviators during the war that when it was found that both eustachian tubes were inefficient and both tympanic membranes were compressed inward there was deafness without vertigo but that when only one eustachian tube was obstructed vertigo was prominent, owing to heterogeneous stimuli. Richey⁶ noted similar observations on pilots who had attacks of vertigo and nausea, after high flying, due to unilateral obstruction of the eustachian tube.

I have made an interesting observation in several instances during the treatment of these patients which proves quite conclusively that the vertigo and nausea are the direct result of the eustachian obstruction. In some instances in which there was marked obstruction it has been possible to reproduce severe attacks of vertigo during inflation, and these have been relieved promptly by passing a bougie to allow air to escape from the middle ear and thereby to relieve the increased pressure produced by inflation. From this it would appear that the perilymph is disturbed by abnormal variations in pressure, either increased or decreased.

In many of the cases it has been noted that the staggering is in the direction of the obstructed side, although this has not been invariably true, according

to my observations. At any rate the direction of the gait furnishes a clue as to the side which may be affected.

SUMMARY

Vertigo caused by obstruction of the eustachian tube is a distinct clinical entity which is often overlooked. An experience in the treatment of 135 cases of this type has proved that distressing symptoms of vertigo, nausea and vomiting, sometimes present for long periods, can be relieved by mechanical inflation of the eustachian tubes. Since obstruction of the eustachian tube is one of the most obvious and also the most easily corrected causes of vertigo, every patient with dizziness and nausea should be subjected to the therapeutic test of inflation of the tubes as a first step in a thorough clinical investigation.

In this series approximately two thirds of the patients were women. Approximately half were between 40 and 60 years of age. The obstruction of the eustachian tubes was associated with acute or chronic inflammation of the nasal sinuses or ears in a large proportion of cases. The duration of the symptoms varied from a day or two to several years.

The symptoms may be of sudden onset or the condition of vertigo may develop gradually and intermittently. In the latter type the true cause of the difficulty is often overlooked and the patients are subjected to a variety of treatments for supposed disorders of the digestive system which yield no benefit.

Some patients are relieved permanently by only one or two inflations of the eustachian tubes; in other cases, the symptoms recur and may again be relieved by reestablishing the patency of the eustachian tube. In addition to the mechanical procedure of inflation, proper treatment of these patients demands attention to chronic sinus infections and chronic tonsillitis, to possible allergic factors and irritants, such as tobacco, and an investigation of the basal metabolic rate.

The vertigo is caused in most instances, and perhaps in all, by unilateral eustachian obstruction or by more complete obstruction on one side than the other. The direction of the gait furnishes a clue to the side which may be affected, for in most of the cases the staggering is in the direction of the obstructed side.

Energy Metabolism.—Accurate measurements by means of the calorimeter have shown that the average total metabolism of a man sitting still is about 100 calories per hour; while the same man working actively increases his metabolism up to about 300 calories per hour; and a well trained man working at his maximum capacity metabolizes material enough to liberate 600 calories per hour, i. e. his metabolism may be six times as active during the hours actually spent in such work as when he is at rest. If during twenty-four hours a man works as hard as this for eight hours and spends two hours in such light exercise as going to and from work, his food requirement for the day will be somewhat over 6,000 calories, or three times the maintenance requirement. Thus, work may increase the day's metabolism as much as 200 per cent, whereas liberal feeding at the end of a fast was found to increase the metabolism only 22.5 per cent, or one ninth as much. Only a few exceptional occupations, such as that of lumbermen, for example, involve such heavy work as to cause a metabolism of 6,000 calories per day. More often the man who works eight hours a day at manual labor will increase his metabolism by 1,000 to 2,000 calories above what is needed for maintenance at rest, making his total food requirement 3,000 to 4,000 calories.—Sherman, Henry C.: *Chemistry of Food and Nutrition*, New York, Macmillan Company, 1941.

APPENDICAL PERITONITIS

EXPERIMENTAL AND CLINICAL INVESTIGATIONS
INTO THE CAUSES OF THE HIGH
MORTALITY

H. B. TRACHTENBERG, M.D.

AND

A. E. PEARCE, M.D.

PHILADELPHIA

The most effective means of reducing the high mortality of appendical peritonitis is the prevention of perforation of the acutely inflamed appendix by teaching the public the dangers of taking laxatives and delaying hospitalization in the presence of abdominal pain. These investigations have already been reported under the prophylactic aspect of the Philadelphia plan.

The scientific aspect presented here includes experimental and clinical research to develop an improved management of patients suffering with spreading peritonitis and to provide continuous research toward further improvement.

The dog has proved to be well adapted for experimental investigations because:

Peritonitis similar to that observed complicating acute appendicitis in man can be induced in the dog by ligating the mesentery and the base of the appendix and administering castor oil immediately after operation.¹

Gross tissue reactions in the dog following the induction of gangrene of the appendix are similar to those observed in gangrenous appendicitis in man.

Changes in the cellular content and chemical composition of the blood and peritoneal exudate preceding rupture and development of the localizing or spreading process are similar in man and dog.

Symptoms and signs accompanying micro-organismal invasion of the peritoneal cavity are likewise similar in the two species.

Recovery from spreading peritonitis in man is preceded or accompanied by the development of an abscess. The dog that recovers from induced spreading peritonitis also develops an abscess which is absorbed.

Death occurs in both man and dog because the reactive capacity of their tissues to the micro-organismal invasion is inadequate.

As these similarities were recognized, the practicality of using the reactions in the dog to measure the value of different methods of management of appendical peritonitis in man became evident. Variables are few. The incidence and mortality of peritonitis in dogs could be varied by withholding or changing the time of administration or the amount of laxatives following ligation of the appendix; without administration of a laxative, 50 per cent of the dogs recovered after an appendical abscess had developed; when 30 cc. of castor oil was given twenty-four hours after operation 68 per cent died; when 60 cc. of castor oil was given immediately after operation 91 per cent died.

Of the patients admitted to hospitals in Pennsylvania with a diagnosis of acute appendicitis or appendical peritonitis, 3,427 had not received laxatives and only 1 in 62 died; 5,868 had taken one laxative and 1 in 19 died; 921 had taken more than one and 1 in 9 died.

From the Foundation for Clinical and Surgical Research and the Philadelphia General Hospital.
The authors received assistance from Dr. J. H. Clark, Chief of Laboratory, and J. G. Reinhold, Ph.D., of the Philadelphia General Hospital.
1. Bower, J. O.; Burns, J. C., and Menzies, H. A.: Induced Spreading Peritonitis Complicating Acute Perforative Appendicitis, *Surg., Gynec. & Obst.* 66: 947-961 (June) 1938.

Man and dog react similarly to surgical procedures instituted in the presence of localizing or spreading peritonitis. Dogs invariably die soon after operations performed during the active stages of an induced peritonitis, and death occurs earlier and more frequently in man when removal or attempted removal of the appendix is instituted before the peritoneal infection becomes localized.²

Likewise, the investigations of agents for combating the toxemia of spreading peritonitis showed that those which produced the lowest mortality in dogs reduced the mortality in man in the same degree when the method of administration and dose were the same.³

Of the 180 dogs treated for induced peritonitis, the lowest mortality was obtained in the group treated with lyophilized serum obtained from the blood of dogs recovered from spreading peritonitis.¹ A group of patients treated identically with lyophilized convalescent peritonitis serum showed a decided improvement over any other form of treatment. That the cellular elements of the blood played little or no part in their improvement is shown by the fact that dogs with spreading peritonitis treated with direct transfusions of whole blood showed no improvement. In fact, in one such group the mortality was even higher than in the untreated group.³

We had used lyophilized convalescent peritonitis serum from 1935 to 1940, at which time we changed to lyophilized plasma in the treatment of spreading peritonitis in man, thereby eliminating delay and technical difficulties. It can be given immediately after the diagnosis has been made. Pooling diminishes reactions, and we have kept ampules of plasma at room temperature as long as fifteen months. Mahoney,⁴ Bond and

Following the intramuscular injection of lyophilized convalescent peritonitis serum we observed that intestinal peristalsis occurred earlier than with any of our previous forms of treatment. Later, however, when lyophilized convalescent plasma was given intravenously

TABLE 2.—Observations in a Case of Appendical Peritonitis

Date	Hemoconcentration	Hemoglobin	Protein	Albumin	Albumin/Globulin	Chlorides	Carbon Dioxide		
5/27/41.....	47.5	15.5	7.0	4.4	1.7	550	54		
5/28/41.....	31.6	12.2	4.8	3.0	1.6	590	52		
Hemoglobin	Red Cells	Leukocytes	Myelocytes	Juveniles	Stab Cells	Segmented Cells	Lymphocytes	T. Polymorphonuclears	
5/27/41	10.5%	5,350,000	7,600	0	0	12%	63%	75%	25%

peristalsis returned even earlier and, in addition, its return was followed by the spontaneous evacuation of intestinal contents, occasionally at the end of eight and not infrequently within twenty-four hours after administration. Investigations by one of the members of our group to determine the cause of this early return of intestinal tonus showed that peritonitis induced in the dog by the method described³ is followed by a loss of plasma and blood volume with attendant loss of plasma protein and electrolyte. Dependent on the degree of loss of plasma there is an early increase in the concentration of the cellular elements of the blood. Fluid present in the peritoneal cavity contains large amounts of plasma protein and accounts for most of the loss of plasma. The most acute changes occur within twenty-four to seventy-two hours after operation. Following this critical stage of the infection there is an extended period of anemia.

In man, changes almost identical with those observed in the dog occur in the blood and the composition of the peritoneal exudate in perforative appendicitis and in the localizing process⁵—early appendical rupture quarantined by fibrinous plaques or mesentery, or loops of intestine cemented together with plastic exudate.

Table 1 shows not only the similarity of these changes but that pathologic changes of similar character in both man and dog evoke similar physiologic responses.

In patient E. K., with gangrene of the appendix, and in dogs 39 and 93, the total protein and albumin contents in the blood and peritoneal exudate were almost identical. In both dogs the process had gone one step further than in patient E. K.—the serous coat of the appendix had perforated but the process had been walled off with omentum and loops of intestine cemented together with plastic exudate—the localizing process.

The concentration of the cellular elements and the chemical changes in the blood and peritoneal exudate in the dog have been studied in detail and reported.⁶

Hemoconcentration with associated changes in the plasma protein is observed early in appendical peritonitis and is illustrated by the following:

J. M., a man aged 28, admitted with symptoms and signs of spreading peritonitis of seventy-two hours' duration, had a temperature of 103 F., a pulse rate of 106 and a respiratory

rate of 28. Perforation had occurred four hours before admission. Despite septicemia produced by *Escherichia coli*, the patient recovered following the administration of 1,750 cc. of lyophilized peritonitis plasma.

COMMENT

The blood changes occurring in acute appendicitis and appendical peritonitis in man and dog are similar to those observed in shock. Blalock,¹⁰ in his investigation of the relationship of the local loss of fluid and low blood pressure, showed that the protein content of the fluid which accumulated and escaped through the wall of the intestine of dogs, accompanying shock induced by intestinal trauma, was practically identical with plasma. Patients suffering with the shock syndrome here described present a somewhat different picture from that which surgeons encounter in the terminal stages of a spreading peritonitis. Increased permeability of capillaries is a common accompaniment of shock and escape of fluids from damaged capillaries can be readily understood. Nerve impulses are believed by O'Shaughnessy and Slome¹¹ to play an important part in the causation of shock. The passage of fluid into the peritoneal cavity in cases of appendical peritonitis may be the result of absorbed bacterial antigens acting on terminal ganglions.

We have reported the finding of the antitoxin to *Clostridium welchi* in the peritoneal exudate of a patient operated on for a localizing process. The patient's blood serum also showed the presence of antitoxin to *Clostridium welchi*.¹²

We believe that the passage of fluid from the vascular system into the peritoneal cavity in preperforate appendicitis and appendical peritonitis is definitely a protective process. To view it otherwise, one must admit that the absence of peristalsis, the presence of plastic exudate between loops of intestine and omentum cementing them together or of antibodies in the blood stream are not protective. If these deductions are correct, then plasma taken from patients recovered from an attack of appendical peritonitis should have more therapeutic value than plasma taken from normal persons. Soon after we started using lyophilized plasma the full significance of the changes in blood composition became apparent. However, additional clinical and experimental investigations will be necessary to determine the relative therapeutic value of lyophilized convalescent peritonitis plasma as compared with lyophilized normal plasma. The following deductions regarding the results of our clinical experience with lyophilized convalescent peritonitis plasma to date may be helpful to those interested in this problem:

INDICATIONS AND CONTRAINDICATIONS FOR THE USE OF LYOPHILIZED CONVALESCENT PERITONITIS PLASMA

Plasma is indicated when a distended, purulent, gangrenous appendix ruptures at operation; when a perforated appendix is unexpectedly found at operation; when a frank spreading peritonitis is present on the patient's admission to the hospital; when an induced spreading peritonitis develops following the search for or removal of an appendix in the presence of a localizing process or an appendical abscess; when spreading peritonitis is induced postoperatively;¹ when peritonitis

develops as a result of ruptured duodenal, stomach or typhoid ulcers, perforation of the gallbladder, intestinal obstruction, salpingitis, abdominal trauma, and like conditions.

The initial amount given intravenously over a period of two hours has been 250 cc., except when an appendix ruptures on removal or for any other reason the patient has been subjected to an extremely large dose of antigen, under which conditions 500 cc. has been given. While the patient's pulse, temperature and the presence or absence of peristalsis are guides to further administration of plasma, protein determinations are also necessary and should be made ten hours after each dose. If symptomatic improvement does not occur, the dose should be repeated at twelve hour intervals until there is improvement. If there is no change in total protein and an improvement of symptoms continues, plasma is withheld.

In addition to plasma, the Fowler position, absolutely nothing by mouth, the parenteral administration of dextrose in saline solution or distilled water, depending on the level of plasma chloride, and morphine hypodermically are advised. Drugs that stimulate peristalsis should not be given at any time. Blood transfusions should not be given during the first forty-eight hours because of early hemoconcentration. Laboratory work will indicate later requirements.

Plasma is contraindicated for patients coming to operation with an unruptured appendix unless symptoms and signs of a peritonitis develop; for moribund patients unless the physician in charge believes that this type of patient should be "given a chance." Then a small blood transfusion is advised and, if the patient reacts, plasma may be administered, alternating with small transfusions. Facilities should be available for protein and hematocrit determinations.

OBSERVATIONS ON THE RESULTS OF THE ADMINISTRATION OF LYOPHILIZED CONVALESCENT PERITONITIS PLASMA

We have not observed as decided a psychic improvement from the administration of any agent in peritonitis as that which follows the intravenous injection of convalescent peritonitis plasma. We mention this first because in our experience it has been the initial change—patients voluntarily comment on how much better they feel. Restlessness and mental irritability diminish or disappear and delirium rarely develops.

Reduction in pulse rate and a drop in temperature are usually gradual in the case of severe involvement but not infrequently precipitous in the case of moderately severe involvement. In a previously silent abdomen peristaltic sounds have been heard as early as eight hours. Rigidity has diminished concomitantly in the quadrants in which peristalsis has returned.

We cannot state definitely the part that antibodies play in the improvement in symptoms and signs noted. The accurate replacement of fluids and electrolytes in quantities that approach as nearly as possible the patient's requirements is extremely important.

SUMMARY

Induced peritonitis in the dog produces tissue and body fluid changes similar to those observed in cases of appendical peritonitis in man, making possible the evaluation of agents used to combat the toxemia.

Preperforative appendicitis and appendical peritonitis in man and induced peritonitis in dogs show blood and body fluid changes similar to those observed in cases of shock.

The intravenous administration of lyophilized convalescent peritonitis plasma is advised in the treatment of patients suffering with appendical peritonitis.

The best management of these patients or of patients suffering with peritonitis from any cause can be carried out only with the aid of a competent clinical biochemist, on whose determinations the institution of therapy in great part depends.

Blood transfusions should be replaced by infusion of human plasma in the early stages of peritonitis.

The convalescent stage of peritonitis is accompanied by hypoproteinemia and anemia.

Lyophilized convalescent peritonitis pooled plasma makes immediate administration possible and diminishes the likelihood of reactions, and the lyophilization does not affect the specific antibody content of plasma.

CONCLUSION

A prophylactic plan for the reduction of the mortality of appendical peritonitis, which has proved workable in Pennsylvania, has been presented; we here suggest to surgeons a plan of management of this disease the rationale of which we believe to be sound.

NOSE DROP CONTAMINATION IN DROPPER BOTTLES

JOHN L. GOMPERTZ, M.D.

AND

PAUL MICHAEL, M.D.

OAKLAND, CALIF.

What lurks in dropper bottles besides nose drops has long been a subject of discussion. By "dropper bottle" is meant the standard type of dropper attached, screw capped bottle wherein the dropper hangs submerged in the solution. The patient purchases a dropper bottle of solution of one of the common vasoconstrictors, treats his cold, then puts the bottle away in the family medicine cabinet. It is brought out thereafter when any member of the household has a stuffy nose. The dropper is inserted into the offending nostrils and is then put back into the bottle. Usually the dropper has been inserted well into the nostrils; therefore the questions arise of nose drops being a possible source of transmission of infection from one member of the family to another and of a future "cold" being complicated by the use of nose drops contaminated from a previous "cold."

Most persons would not think of borrowing another person's toothbrush, but perhaps nose drops in dropper bottles are cleaner than toothbrushes and won't support living bacteria. Therefore the following examinations of the contents of dropper bottles were made in the clinical laboratories of Peralta Hospital.

Eight unused, regularly prescribed dropper bottles of solutions for intranasal use were obtained from the hospital pharmacy (table 1). All solutions contained a preservative in small amount or were rich in aromatics. All were cultured aerobically and anaerobically and no growth appeared at the end of ninety-six hours. Fresh unused samples were then inoculated with twenty-four hour broth subcultures of *Staphylococcus aureus* hemolyticus and no growth appeared at the end of ninety-six hours, even after a second inoculation. Then rabbit blood-agar plates were inoculated with broth cultures of the same organism and four hours later, before a visible growth had occurred, the plates were

flooded with the solutions from dropper bottles. At the end of twenty-four hours a luxurious growth of *Staphylococcus aureus* appeared almost equal to the control plates that were not flooded with the solutions.

Thus it would appear that vasoconstrictor solutions in dropper bottles are probably sterile as dispensed by the pharmacist. Such solutions resist bacterial growth either by slight inhibition or by failure to provide sufficient nutrient material. As no bactericidal effect was demonstrated, lack of nutrient material is the more likely. Bacteriostatic effects were almost negligible.

Contents of dropper bottles known to have been used by one or more persons for at least one week were now examined. Nineteen samples were collected from as many medicine chests. Seven of these were commercial ephedrine solutions; twelve were of neosynephrin. All contained a preservative or aromatics. All yielded bacterial growth on culture (table 2).

Apparently repeated passage of the dropper from nostril to solution had succeeded in each instance in establishing bacterial growth. The explanation might be the addition of mucus, pus and debris to the solution as nutrient material, or it might be that bacteria continued to live within the added particles out of reach of the slight concentration of antiseptic in the surrounding solution.

As significant as any of these observations, however, and with the additional importance of probably supplying one answer to the problem, was the following:

Six samples from bottles containing physiologic solution of ephedrine without any antiseptic or dropper but with plain screw caps showed no bacterial growth on culture. These were bottles from separate medicine cabinets, and in all instances the contents had been partly used. But in no instance had a dropper been

introduced into the bottle. In all instances portions had been removed only by unscrewing the cap, pouring out an amount needed for treatment and replacing the cap.

COMMENT

The question of sterility of solutions for intranasal use is important and there is an answer. The answer does not lie in avoiding the issue by the use of stronger

antiseptics. It lies in sterile solutions correctly dispensed and correctly used. Nor can medical practice make one grand effortless leap from the era of antiseptics to a new era of asepsis. Such change requires appropriate increases in education, instruction and care.

TABLE 2.—Composition of Nose Drops Examined and Organisms Found on Culture*

19	Neosynephrin 0.25%	Aqueous	Sodium benzoate 0.1%	Eucalyptol, menthol	Hemolytic Staphylococcus aureus

* All of these solutions were used at least one week.

Perhaps it does not make any difference to a person if he repeatedly uses his contaminated nose drops during that particular infection. But in his next cold the complicating organism may be a different one and the instillation of the first type of bacteria on a weakened mucous membrane may add to the patient's complications.

Staphylococci themselves may not cause actual disease of the upper respiratory tract if the mucous membrane is healthy; however, staphylococci may complicate another type of infection by synergistic action. The presence of staphylococci in nose drops may also indicate other contamination such as virus. No study was made of the possibility of virus growth in nose drops in this investigation. Surely it is a possibility that should not be overlooked.

In the series of samples tested, there were various preservatives and antiseptics used. These did not prevent bacteria from living in the nose drops. If a sufficient concentration of preservative or antiseptic was added to keep the drops sterile, the drops would be irritating and harmful to the mucous membrane of the nose.

The main purpose of this paper is to condemn two practices that are widespread among the public and are at times fostered unintentionally by physicians. These are (1) the use by a patient of some one else's dropper bottle of nose drops and (2) the use by a patient of dropper bottle nose drops that he has used during a previous infection of the upper respiratory tract.

In order to avoid the complications of these practices, the physician should educate his patients to do one of two things: If they insist on buying dropper bottles of solution, they should buy very small ones, allow no one else to use them and throw them away at the conclusion of their current infection.

However, the safer and better method is to buy sterile nose drops containing no antiseptic, in a plain screw cap bottle. Instruction is given to pour out the amount needed for treatment and replace the screw cap at once, never pour anything back into the original bottle and never put a dropper or anything else into it. This is the practice advocated by Parkinson.¹

Even with the few instances involved in this investigation, certain conclusions can be drawn that are highly significant in relation to present customs of dispensing and using vasoconstrictor solutions for intranasal application.

SUMMARY

1. Fresh nose drops as they are dispensed are probably sterile.

2. The usual content of preservative or antiseptic is insufficient to maintain sterility in the face of repeated contamination.

3. Many popular intranasal vasoconstrictor solutions have no bactericidal effect on Staphylococcus aureus hemolyticus.

4. Repeated contamination of nose drops results in their supporting living bacteria. This probably is due to the addition of mucus and other debris from the nose.

5. The use of contaminated dropper bottle contents by others, or in subsequent colds, is not without risk.

6. Since sufficient antiseptic to insure sterility under circumstances of repeated contamination would make a solution unfit for intranasal use, owing to discomfort and mucosal irritation and damage, the way to progress would seem to be toward solutions prepared, sold and used in such manner as to avoid contamination.

THE GRID FOR EVALUATING PHYSICAL FITNESS (WETZEL)

APPLICATION TO CHILDREN WITH ABNORMAL BODILY DIMENSIONS

HILDE BRUCH, M.D.
BALTIMORE

In a recent publication Wetzel¹ described a new method for evaluating physical fitness which permits the estimate of different aspects of the physical progress of a child from infancy to maturity. The assessment is based on the use of a grid and demands only three simple routine measurements, namely height, weight and age. Wetzel enumerates eight different items which may be determined from the grid: physique (body build), developmental level, nutritional grade, physical status, relative advancement or retardation, maturation, basal heat production and daily caloric intake. The technic is described in detail in the original publication and will not be repeated in this paper. The different aspects are explained by illustrative examples. Yet no examples are given which show the interrelation of the different aspects in the same individual, specifically not in individuals with abnormal bodily dimensions.

The present report is intended to illustrate the application of the grid to children in whom one or more of the basic measurements is distorted. Since in this department records of more than 200 obese children, with relevant measurements, are available, the discussion will concern itself chiefly with findings in obese children. Cases of pronounced undernutrition and of retardation or acceleration of statural growth are included for contrast. The value of the method for recognition of abnormal physical status and for evaluation of therapeutic results could be confirmed. However, some limitations of the method, which were not clarified in the original report, have been observed. For simplification the eight aspects recorded by Wetzel will be discussed under three different headings: (1) height-weight relationship (including physique, nutritional grade and physical status), (2) developmental achievement (including developmental level, relative age advancement or retardation and maturation) and (3) basal metabolism (basal heat production and daily caloric intake).

HEIGHT-WEIGHT RELATIONSHIP

The construction of the grid permits the recording of height and weight by a single point. The area of normal progress is divided into several channels. If subsequent measurements follow the course of one of the established channels it may be concluded that the child is healthy and is progressing normally. The body build of a child determines the particular channel along which his growth line progresses. Abnormal increase in weight expresses itself in an upward trend of the line, or deviation toward the left. Malnutrition is indicated by a lowering of the line, or a bending toward the right side of the grid. Wetzel describes extensively the usefulness of the grid for the early detection of developing obesity or malnutrition. The value of the new method could be fully confirmed in

a large group of children with abnormal nutritional status. The graphic registration on the grid appears to be of particular value in detecting sudden changes in the height-weight relationship and will thus lead to an early investigation of the disturbing factors.

By plotting a number of cases which had been followed for several years, the value of the grid for a quick evaluation of the result of treatment could be demonstrated. Since obesity generally requires long-continued supervision and since a certain increase in weight is to be expected in a growing child, the appraisal of the progress of an obese child is sometimes difficult. It is only in the decidedly overweight child that actual reduction of weight is indicated. In less severe cases it may be sufficient to keep the weight stationary or even to allow a slight increase in weight. By transferring the figures to the grid, one can readily recognize whether or not a child is outgrowing his obesity. A slope of the line smaller than the slope of the grid indicates satisfactory progress and improvement of the condition. A parallel curve of the line or a slope larger than that of the grid is an index that the condition is stationary or is becoming worse. The grid thus offers a convenient guide for the evaluation and adjustment of treatment in children with abnormal nutrition.

DEVELOPMENTAL ACHIEVEMENT

The channels indicating height and weight progress are subdivided by so-called developmental lines. These lines are related to standard schedules of developmental progress ("auxodromes"). Comparison of the developmental level of a subject to the 67 per cent (or normal) auxodrome permits, according to Wetzel, a "simple, entirely objective," way of determining "developmental age." This measurement is claimed to be comparable to the skeletal age. Wetzel emphasizes that the new method avoids the disadvantages connected with roentgenographic determinations of skeletal age. However, he gives no figures which demonstrate the validity of this claim in children with abnormal bodily dimensions. A comparison of the developmental level, determined from the grid, and of the skeletal age, as measured by the traditional roentgenographic method, must show a good agreement before one is justified in replacing a well established, though tedious, method by a new and simpler one.

The accompanying tables show the result of such a comparison. Table 1 lists observation in 25 obese boys, and table 2 in 20 obese girls. The figures are intended to give the range of variation with regard to age and degree of obesity. The first difficulty in rating the patients according to the grid technic arises from the circumstance that many of the older and decidedly obese children fall outside the range which can be assessed from the grid. There are only 2 girls of more than 9 years who could be included; they were the shortest obese girls of this age period. The values of all other obese girls of more than 10 years fell above the developmental line 147, which is the highest value which may be related to the 67 per cent or normal auxodrome. Many of the older boys had also to be rejected because their height and weight gave them a developmental level above 170, which is approximately the highest value which can be expressed as developmental age.

In tables 1 and 2 are recorded the age, height and weight of the children together with their skeletal age. The assessment of the skeletal age was made from

From the Department of Pediatrics, Columbia University College of Physicians and Surgeons.
1. Wetzel, N. C.: Physical Fitness in Terms of Physique, Development and Basal Metabolism, *J. A. M. A.* 116: 1187 (March 22) 1941.

roentgenograms of the hands and wrists according to the standards of Todd.²

The "developmental age" was assessed according to Wetzel's description as the age that corresponds to the 67 per cent auxodrome. "Height age" was similarly determined by plotting the height in the median channel and referring it from there to the 67 per cent auxodrome. The figures for height age enclosed in parenthesis have

than twice the value of the observed skeletal age. The discrepancies between the different determinations is illustrated in chart 1. The abscissa refers to the chronologic age, the ordinate refers to height age, skeletal age and developmental age, each of which is plotted above the chronologic age for each child. The 45 degree line indicates equality between chronologic age and the determined growth achievement. The majority of

been assessed from the height charts of Burgess³ because the values fell below the range of the 67 per cent auxodrome. "Per cent overweight" refers to the difference between observed weight and expected weight, the latter being taken as the weight which, according to the grid, corresponds to the height in the median channel.

A glance at tables 1 and 2 shows that little agreement exists between the "skeletal age," according to the roentgenographic method, and the "developmental age," according to the grid. In all instances the developmental age gives a much higher value, sometimes more

values fall above this line, indicating accelerated physical development in obese children.⁴ The values for height and skeletal age fall generally within two or three years of the chronologic age. The height development is on the average somewhat more accelerated than the skeletal maturation. But the two values fall within the same zone, indicating a proportional acceleration of development in obese children.

The values for "developmental age" calculated according to the grid lie well above the values for height and skeletal development and are out of proportion with the actual biologic development of the child. The discrepancy is the more pronounced the higher the per-

centage of overweight. The dependence of the excessively high value for developmental age on the weight excess is illustrated in chart 2. On this chart the percentage overweight is plotted against the difference between developmental age and height age. The direct relationship between the excessively high value

Chart 1.—Relation between chronologic age, skeletal maturation and "developmental age" (Wetzel) in obese children: The abscissa indicates chronologic age in years, the ordinate the achievement in different growth phases. The 45 degree line indicates equality (normal development) between chronologic and achievement age. Skeletal age is represented by solid dots, height age by open circles, and developmental age by circles with a center dot.

for developmental age and the excessive weight is obvious. The deviation from the height age, and not the skeletal age, was chosen for comparison because both the height and the developmental age, and also the weight excess, were calculated from Wetzel's grid. These three values are therefore directly comparable. The deviation from the skeletal age would show somewhat higher values; yet the relationship to the weight excess would be very similar.

Further observations were made in nonobese children with other distortions in height or weight development. They are presented in table 3. Cases 1 and 2 represent 2 tall and thin children, both of whom have a normal skeletal age. The rating on the grid gave them too low a developmental age. In the third case (table 2) the height development is so excessive that it compensates for the low weight and leads to too high a value for developmental age. This child also has a normal skeletal age.

Two abnormally short patients are presented as cases 4 and 5. In these patients the height-weight relationship is normal; therefore the height age and developmental age from the grid show good agreement. Yet the skeletal age was in 1 case below and in the other above the value assessed from the grid.

Finally, figures are given for 2 girls with hypothyroidism who had been inadequately treated. Both were short but of stocky body build. In both cases

the rating from the grid gave a developmental age in excess of the actually observed skeletal age.

The examples of tables 1, 2 and 3 were taken at random from a large group of children with some abnormal bodily dimension, who had been extensively studied. In no case did the "developmental age" according to the grid agree with the assessment of the skeletal age, according to the roentgenologic determination. The "developmental age," distorted by the inclusion of the abnormal dimension, gives too high or too low a value. Wetzel's claim that the "developmental age" may serve the same purpose as the skeletal age could not be verified in these 52 children. Yet it is in children of this type that the correct assessment of the developmental achievement is of diagnostic and prognostic importance.

Many of the children in tables 1, 2 and 3 have been followed for several years. Their subsequent puberal development has confirmed the value of the skeletal age for arriving at a fairly accurate prediction of further development. In none of these cases would the assessment of the "developmental age" have given a reliable prediction about the time of maturity.

BASAL METABOLISM

The heat production scale of the grid is given in conjunction with the developmental levels. Since the developmental levels were found to be directly influenced by the abnormal bodily dimension, it is obvious that the same must be expected for the prediction of basal metabolism, in contrast to the claim that "the present method offers the encouragement that clinical distinction between normal and abnormal states of metabolism can be made with greater accuracy and less uncertainty than before" and "without correcting for body size, physique or age." This statement may hold true for normal children; it could not be validated for children with abnormal bodily dimensions. The same problems which apply to the use of other standards arise also with the diagnostic application of the new standards.

Chart 2.—The relationship between degree of obesity and the excessive value for developmental age: The abscissa indicates the weight excess in percentage, the ordinate the difference between developmental age and height age. All these values were calculated from the grid. Values for boys are represented by solid dots, for girls by open circles.

In tables 4 and 5 are presented observations on 20 obese boys and 20 obese girls who were chosen at random (with the exception that a number of patients fell outside the given scale). The observed caloric

output is given in comparison to the predictions from Wetzel's new standards and Talbot's weight standards.⁵ The correlation coefficient between the two predictions is very high, namely 0.95. Both standards give too high predictions for very young children. There is no reason to suppose that the deviation in these young children is an expression of abnormal metabolism any

standards were observed. The correlation coefficient between the two standards was higher than that between each standard and the observed calories (0.81 and 0.77 respectively). One may conclude that in obese children the abnormal dimension (the excessive weight) enters into the calculation of the basal metabolism and cannot be disregarded.

more than to conclude that the agreement in the older children between the observed calories and both Wetzel's and Talbot's weight standards is necessarily an expression of normal metabolism. Wetzel's standards gave a slightly better result in an unusually tall boy (case 10, table 4) and in a rather short but very heavy boy (case 16, table 4). No other conspicuous differences between the predictions from these two

standards were observed. The correlation coefficient between the two standards was higher than that between each standard and the observed calories (0.81 and 0.77 respectively). One may conclude that in obese children the abnormal dimension (the excessive weight) enters into the calculation of the basal metabolism and cannot be disregarded.

In the 2 hypothyroid patients (cases 6 and 7, table 3) the prediction from the grid was higher than the observed calories. In these 2 patients the interpretation

⁵ Talbot, F. B. Basal Metabolism Standards for Children, *Am J Dis Child* 55:455 (March) 1948

of the observed metabolism as "low" may be justified but only because the retarded skeletal age (supported by the clinical history and other findings) points to hypothyroidism as the underlying disturbance. The assessment of the "developmental level" from the grid, which was found to be higher than the height age, would not have permitted this diagnostic conclusion. The other customary standards give also a low rating in these children with true hypothyroidism.

SUMMARY AND CONCLUSION

1. The grid for evaluating physical fitness (Wetzel) was applied to 52 children with abnormal bodily dimensions. The usefulness of the new method for the graphic recording and early recognition of abnormal changes in the height-weight relationship could be confirmed. The grid appears to be of value for the appraisal of therapeutic results.

2. The relative advancement or retardation of statural growth ("height age") can be readily assessed with the aid of the auxodromes.

3. The assessment of the "developmental age" from the combined height and weight value was found to show no agreement, in any instance, with the roentgenographically determined skeletal age. Clinical observation has proved the skeletal age to be fairly reliable for the prediction of the future development and maturation.

4. The deviation of the "developmental age" could be directly related to the abnormal physical dimension. The assessment of the "developmental age" from the grid leads to an unreliable prediction of maturation.

5. Since the standards for basal metabolism predictable from grid readings are alined to the developmental levels the same limitations apply to them. They also are influenced by the abnormal bodily dimension and should not be used for the assessment of abnormal metabolic states without correction for and consideration of the abnormal dimension.

6. It was considered necessary to point out the limitations of the new method in order to bring into clearer relief the true usefulness of the method. It is to be expected that the application of the grid in public health work, school examinations and so on will render valuable service in screening out children with abnormal body proportions and disturbances in developmental progress. For the diagnosis, however, of the underlying disturbance in such children, and for the prediction of future development and maturity, the assessment of "developmental age" and also of basal metabolism from the grid offers only unreliable information.

Assistant in Surgery, Respectively, Loyola University
School of Medicine

CHICAGO

Within the past two decades the obliteration of varicose veins by the injection of sclerosing solutions has become an accepted form of treatment. This may be associated, however, with a certain amount of danger, regardless of the fact that it is being and has been employed daily in the treatment of thousands of patients with no resulting serious complications. Serious reactions to the injection of sodium morrhuate have been encountered by Lewis,¹ Dale² and McCastor,³ as noted in a previous publication by one of us.⁴

Pulmonary embolus from the left common iliac vein.

In the case reported, death was proved to be due to pulmonary embolism. While this is undoubtedly the most serious complication to be feared, it is possible that allergy to sodium morrhuate plays a role in some of the reactions observed. This could conceivably be related to an acquired sensitivity from the previous administration of cod liver oil. For this reason it is important to question the patient concerning asthma, hay fever or other manifestations of allergic predispositions, as well as concerning previous sodium morrhuate injections. In addition to this a sensitivity test with sodium morrhuate should be made or a small initial injection given.

Our aim in this paper is to show that a fatal complication may occur unless certain precautions are taken. The case report and a review of the fatal cases reported by other clinicians may help to prevent this tragic sequel to a popular method of treatment. It is probable that more fatal cases have occurred but have not been reported.

Insurance Against Misuse of Science.—It is a stimulating challenge to have others say that there is too much science in the world. It is my opinion that we have too little of the scientific spirit in those who use the discoveries of science! We create machines and they are allowed to exploit people. Every tool and machine should have a tag attached as when a mechanic finishes greasing your car at the garage. The tag should say that you last looked at the social effects of the tool three months or three years ago and that it is time to have another look. Society should require insurance against misuse—for everything that science is and means is wrapped up in its effect on men. Human beings are at the center of it all. Not the thousand and one laboratories and "things" that science produces but rather their social effects are what concern us.—Bowman, Isaiah: Enduring Purpose, *Assn. Am. Coll. Bull.* 26:195 (May) 1940.

REPORT OF CASE

Miss J. T., aged 65, was admitted to the outpatient department of the Mercy Hospital Free Dispensary on March 24, 1936 with a history of varicose ulcers on the left leg and swelling of the left ankle for the past five weeks. The present illness dates back to 1926, at which time she was hospitalized for five weeks because of ulcers of the left leg which evidently

rate 88, the respiratory rate 18 and the blood pressure 140 systolic and 95 diastolic. General physical examination was negative except for a soft, moderately low pitched, apical systolic murmur. The essential pathologic condition was a shallow, tender ulceration the size of a 25 cent piece (24 mm.) over the anterior part of the tibia at the junction of the middle and lower thirds of the left leg, which oozed serum and pus and

completely healed, and she remained symptom free until five weeks prior to the present hospital admission. Aside from this condition the patient had always been in good health and had been able to carry out her duties as a room cleaner, which involved considerable walking and standing. Her father died of a heart attack, her mother of pulmonary tuberculosis and one brother from a "stroke."

Physical examination revealed that the patient was fairly well developed but poorly nourished, intelligent, alert and apparently not in any distress. Her temperature was 99.2 F., the pulse

was surrounded by a reddish blue indurated area of skin. Over the popliteal and patellar regions there was a similar area of reddish blue unbroken skin the size of an elm leaf. The veins in the left leg were enlarged and tortuous. Neurologic examination was negative.

Urinalysis and blood counts were within normal limits, and Wassermann and Kahn tests were negative.

The patient was referred to the Department of Dermatology, where a diagnosis of varicose ulcer and veins was made, and she was then referred to the Department of Surgery for treat-

ment. On March 28, 2 cc. of 5 per cent sodium morrhuate was injected into a varicose vein just proximal to the ulcer and the ulcer dressed with Peruvian balsam. Evidently the ulcer did not improve and on April 14 she was admitted to Mercy Hospital for further treatment and study.

At this time the patient was kept in bed; hot fomentations and a heat cradle were applied. Four injections of 1.5 cc. of 5 per cent sodium morrhuate were given on the 16th, 17th, 18th and 20th of April, all being given in the varicose vein just above the ulcer. After the last injection the ulcer was noted to be healing rapidly. At 6 a. m. on April 28, after sleeping six hours, the patient suddenly became dyspneic and lost consciousness; her pulse was of poor quality and the respiratory rate became slow. A considerable degree of cyanosis developed, and the skin became moist and cold. One ampule of caffeine with sodium benzoate was given without effect, and respirations ceased fifteen minutes after the onset of the attack.

A total of 7.5 cc. of a 5 per cent solution of sodium morrhuate had been given, and death occurred thirty-one days after the first and eight days after the last injection.

Autopsy by Dr. Enstace L. Benjamin revealed essentially a 4 by 4.5 cm. granulating wound on the mesial aspect of the left shin about the middle third. The surrounding skin was indurated and brown red to gray red. The posterior aspect

COMMENT

The first case of fatal pulmonary embolism following the injection of sclerosing solutions for the treatment of varicose vein was reported in 1922 by Hohlbaum.⁵ The first American author to report a fatal case was Olson⁶ in 1927. A comprehensive review of the literature on this subject was first attempted by McPheeters and Rice⁷ in 1928. These authors, after a careful search of the European and American literature, found 4 diagnosed cases of fatal pulmonary embolism in a total of 53,000 cases of varicose veins treated by injection. In 1931 Kettel⁸ reviewed 60,000 cases and reported ten deaths in addition to those reported by McPheeters and Rice. After careful analysis of these deaths, however, only one can be attributed to the present day recognized technic of injection treatment. Silverman⁹ reviewed the literature carefully up to 1931 and found a total of seventeen deaths and added one of his own, making a total of eighteen deaths. His search also revealed 3 nonfatal cases of pulmonary embolism following injection treatment. The literature was brought up to date in 1934 by Kilbourne,¹⁰ who

TABLE 2.—Reported Cases of Nonfatal Pulmonary Embolism Following Injection Treatment of Varicose Veins

No.	Author	Year	Solution Used	Amount	Ambulatory; Bedridden	Result

11	Smith: Mil. Surgeon 85: 514, 1939.....	1939	Sodium morrhuate 5%	2-4 cc. daily	Recovered
12	Smith: Mil. Surgeon 85: 514, 1939.....	1939	Sodium morrhuate 5%	2-4 cc. daily	Recovered
13	Smith: Mil. Surgeon 85: 514, 1939.....	1939	Sodium morrhuate 5%	2-4 cc. daily	Recovered
14	Smith: Mil. Surgeon 85: 514, 1939.....	1939	Sodium morrhuate 5%	2-4 cc. daily	Recovered
15	Smith: Mil. Surgeon 85: 514, 1939.....	1939	Sodium morrhuate 5%	2-4 cc. daily	Recovered
16	Smith: Mil. Surgeon 85: 514, 1939.....	1939	Sodium morrhuate 5%	2-4 cc. daily	Recovered
17	Smith: Mil. Surgeon 85: 514, 1939.....	1939	Sodium morrhuate 5%	2-4 cc. daily	Recovered

of the thigh and knee was dark reddish brown. Both pleural cavities were completely obliterated by firm fibrous adhesions. There were old adhesions between the pericardial sac and the pleural surfaces and diaphragm, and bilateral chronic adhesive and obliterative pleuritis.

The size of the heart was about normal and the valves were essentially normal. The coronary arteries showed a rather severe sclerosis with 40 to 50 per cent reduction in the patency of the lumen. There was a moderate degree of atherosclerosis at the beginning of the aorta, which increased in degree as the abdominal aorta was reached. The endocardium was fairly smooth throughout. The aortic valve leaflets were slightly sclerotic, with cohesion of their free margins at their point of attachment. The corpora aurantis were hard and slightly enlarged. There was a subepicardial sclerosis (soldiers' spots) on the ventral surface of the right ventricle.

Both main pulmonary arteries and their first division were occluded by coiled emboli. The lungs were dark red to gray and hyperemic. There was moderate coal pigmentation. Pleural surfaces were shaggy as the result of fibrous adhesions. The left common iliac vein was distended with blood; its tributaries deeper in the leg were occluded by antemortem clots. Other organs showed no noteworthy changes.

The pathologic diagnosis was bilateral pulmonary embolism; thrombosis of the veins of the left leg and common iliac vein; bilateral pulmonary hyperemia; generalized arteriosclerosis, especially of the abdominal aorta and of the coronary arteries; fibrous obliteration of the pleural cavities; chronic healing ulcer (varicose) of the left leg.

added 9 cases to those already collected by Silverman. Westerborn¹¹ in 1937 reviewed the cases in Sweden and reported eleven deaths in 30,000 cases. In the same year Homans,¹² reviewing one hundred and sixty-two vein ligations for thrombophlebitis at the Massachusetts General Hospital, reported three deaths from pulmonary embolism. In 1940 Dean and Dulin,¹³ reviewing about 600 cases of varicose veins treated by injection at the University Hospitals, State University of Iowa College of Medicine, reported two deaths from pulmonary embolism; they state that in their opinion the danger of embolism is greater than heretofore acknowledged and recommend routine high saphenous vein ligation preceding the injection treatment. Tables 1 and 2 list the reported cases of fatal and nonfatal pulmonary emboli following the injection treatment of varicose veins.

CONCLUSIONS

The injection treatment of varicose veins is not free from complications, which may even be fatal.

Injection of too large amounts of sclerosing solution, as was the vogue in the earlier days of treatment of varicose veins, is dangerous. It is noted from the accompanying tables that 40 to 90 cc. of solution was used in some of the fatal cases. In our opinion, no more than 10 cc. of solution should be injected at any one visit.

Injection in the presence of thrombophlebitis is a potential source of an embolus.

"In the injection treatment of varicose veins, proper selection of cases, skilled technic and the complete cooperation of the patient after the injection in continuing routine daily activities will lessen the frequency of pulmonary embolism."¹⁴

SUMMARY

1. An additional case of fatal pulmonary embolism following varicose vein injection was observed.
2. Bedridden patients should not be injected.
3. It is important to keep patients ambulatory following the injection treatment of varicose veins.

Clinical Notes, Suggestions and New Instruments

SALMONELLA SCHOTTMÜLLERI ISOLATED FROM SACROLUMBAR LESION OF TWENTY-FOUR YEARS' DURATION

E. E. ECKER, PH.D., A. O. KUEHN AND E. W. RECROFT, M.D.,
CLEVELAND

Since Achard and Bensaude¹ established the etiology of paratyphoid fever in 1896, the causative organism and its related species and types have been isolated in numerous instances from abscesses of widely different tissues. The literature, however, offers only 3 doubtful cases in which an organism of the *Salmonella schottmülleri* type has been obtained from infections involving the bones.

Achard and Bensaude were the first also to describe a case of purulent arthritis from which this organism was recovered. In 1900 Cushing² reported the discovery of a paratyphoid bacillus from a costochondral abscess, and in 1916 Gildemeister³ isolated a similar organism from a periosteal lesion of the forearm. There is little assurance that the organisms found in these early cases are of the true *Schottmüller* type. The complex antigenic constitution of this group of organisms was not known and serologic methods of differentiation therefore still were undeveloped.

REPORT OF CASE

History.—A white man aged 36 had been admitted to a hospital for one month with high fever of unknown origin when he was 13. At the end of this time severe pains in the right sacrolumbar region prompted an exploratory operation on that side. Negative results and continued pain suggested that the pain originated from the spine, and a body cast was put on. However, after removal of the cast the pain recurred. He was again placed in a cast, and this cast was reduced gradually over a period of six months. With final removal of the cast the pain had completely disappeared.

From that time on, and up until two years before the present admission, the patient remained well but suffered occasional relapses following any straining of the back. Two years before the present admission the patient was hospitalized for a severe relapse (fever and pain in the back), and again a cast was put on. After removal of this cast, which was worn for eight weeks, a sacrolumbar abscess was uncovered and a culture was taken from the pus, with negative results. The abscess has since opened spontaneously on two occasions and has been aspirated once. Previous to this report, all bacteriologic examinations had given negative results. At the beginning of this year the patient again suffered a relapse and pus was aspirated from the sacrolumbar abscess. The organism recovered will be characterized.

Röntgenologic Examination.—The lesion was found between the fifth lumbar and the first sacral vertebra, involving the end-plates and destroying the intervertebral disks. A large spur was observed on the upper anterior surface of the fifth lumbar vertebral body. The lesion appeared to represent an old infectious spondylitis. An extensive sinus tract was also noted in the left midquadrant, situated retroperitoneally and extending to the subcutaneous tissues of the back but not communicating with either the left kidney or any part of the colon. A possible relationship was believed to exist between the sinus tract and the vertebral lesion, but roentgenologically a communication was not observed between the two processes.

Bacteriologic Examination.—Aspirated pus was inoculated on Endo agar, Wilson-Blair agar, desoxycholate agar, blood agar, Sabouraud's maltose and dextrose agar and Löwenstein's and Petragnani's mediums. At this time pus was injected into the inguinal region of 2 guinea pigs.

From the differential mediums (Endo, Wilson-Blair and desoxycholate agars) a short, thin, motile and gram-negative rod was isolated.

The Sabouraud, Löwenstein and Petragnani mediums showed no growth and at the designated time the guinea pigs failed to show evidence of tuberculousis.

Cultural Characteristics.—On nutrient agar the colonies of the isolated organism compared favorably with colonies of the paratyphoid group. The new strain (Z) failed to produce a slime wall; *Schottmüller* strains generally produce a slime wall. The Z strain also failed to show raffinose budding.

The Z strain did not produce gas in any of the carbohydrates and alcohols in the early cultures. Only after three months did the transplants show a slight amount of gas.

In general, it can be said that the fermentation reactions of the Z strain, with the exception of its failure to attack glycerin and to produce gas, paralleled the accepted reactions of a true *Schottmüller* type.

The Z strain decomposed salts of organic acids, namely sodium citrate and levosodium tartrate but not dextrosodium tartrate. It was capable of reducing nitrates. On Bitter's rhamnose milk the organism changed the methyl red indicator to yellow. On Rothberger's neutral red agar it brought about at first a fluorescence and later a decoloration of the medium. The Z strain produced hydrogen sulfide.

On the basis of its cultural characteristics, then, the Z strain deviated from that of *S. schottmülleri* only in the following respects: (1) It did not exhibit a slime wall, (2) it did not produce budding on raffinose agar and (3) it did not attack glycerin.

Serologic Examination.—All agglutination reactions were carried out according to the macroscopic technic of Coleman. It was shown that the X organism agglutinated in an Eberthella typhi immune serum in dilutions up to 1:40, in a *Salmonella* paratyphi A immune serum in dilutions up to 1:80 and by an *S. schottmülleri* immune serum in dilutions up to 1:2560.

Conversely, agglutination tests were set up with the patient's serum and known organisms. The patient's serum agglutinated the *E. typhi* O, *E. typhi* B, *S. paratyphi* A and *S. schottmülleri* antigens only to a very slight degree (1:20 to 1:40). However, the patient's serum, in dilution up to 1:1,280, agglutinated its homologous antigen (Z). The failure of this serum to agglutinate a known *S. schottmülleri* does not lessen the value of the presumptive test, because in many cases in which *S.*

2. Cushing, Harvey: *Bull. Johns Hopkins Hosp.* 11:156, 1900.

3. Gildemeister, E.: *Centralbl. f. Bakt. (Abt. I)* 78:129, 1916.

schottmülleri organisms have been involved results identical with those observed here have been reported.

Absorption.—Absorption tests were carried out with a diluted immune serum (one-sixty-fourth end titer) in order to eliminate a prozone effect. In every instance the absorption was complete. These tests included the following: (1) The patient's serum was absorbed with *S. schottmülleri* organisms and the absorbed serum tested with *S. schottmülleri* as well as with the Z organisms. 2. The patient's serum was absorbed with the Z strain and the absorbed serum tested with the Z organisms. 3. *S. schottmülleri* immune serum was absorbed with the *S. schottmülleri* and also with the Z strain, and the absorbed serums were tested with both strains.

The Z organisms absorbed all the agglutinins from the patient's serum as well as from the specific immune serum.

Immune Serums Made from the Z Strain.—Rabbits were immunized with H and O antigens of the strain. The Z-H antiserum agglutinated its homologous antigen up to a dilution of 1:10,240, while only weak agglutinations were noted when the Z-O antigen was employed. This serum further agglutinated the *S. schottmülleri* and aertrycke antigens in dilutions up to 1:1,280 and 1:320 respectively. The nonspecific agglutination of the *Salmonella* aertrycke by the Z-H immune serum is explained by the fact that it shares common antigenic factors with the *S. schottmülleri* strain.

The immune serums prepared against the Z-O antigens were not as specific as the immune serums prepared against the Z-H antigens, and agglutinations similar to those described for the Z-H immune serums were employed to determine specificity.

The Z-O immune serum, in dilutions up to 1:320, strongly agglutinated its homologous antigen, while at the same dilution it only weakly agglutinated the Z-H antigen.

When *Salmonella enteritidis* and *Salmonella suipestifer* organisms are employed with the Z-O immune serums, only questionable agglutinations were observed. However, the Z-O antiserum, in dilutions up to 1:160, agglutinated the *S. aertrycke*, which shows the close relationship between it and the *S. schottmülleri*.

Antigenic Analysis.—During the past two decades the serologic differentiation of the *Salmonella* group advanced rapidly and culminated in the splendid works of White⁴ and of Kauffmann.⁵ From these studies it is known that in many members of the *Salmonella* group, including the *S. schottmülleri*, the flagellar (H) antigens are diphasic. In these instances the flagella of the so-called diphasic organisms may assume two alternative forms, namely a specific phase and a group phase. The antigenic components of the specific phase are specific for the particular species or type concerned, or they may be shared by only a few other species or types. The antigenic components of the group phase are, however, shared by many other species or types. A diphasic organism may possess one or both phases. An organism in one phase, although always capable of giving rise to descendants in the alternative phase, usually produces daughter cells having their own particular phase. In any given species or types there may be more than one H antigen (flagellar) in the specific phase. The number of H antigens in the specific phase varies usually from one to four. Generally, several different antigens occur in the group phase, numbering usually from two to four.

In regard to the O antigens (somatic), the majority of species have two components. Some show more than two.

The terminology of Kauffmann was adopted for *Salmonella* by the *Salmonella* subcommittee in 1934.

The somatic O antigens are labeled with Roman numerals, while the specific flagellar H antigens are indicated with small letters of the alphabet. However, the numbers of H antigens soon exceeded the letters of the alphabet, and the later additions were given the symbols of Z₁, Z₂ and so on.

This method of classification is based purely on the antigenic factors, forming no part of the name of any given species or

types. The Z strain was then tested with the serums of Dr. Kauffmann and according to the Kauffmann-White schema; the antigenic composition of the organism isolated in this case is as follows: IV, V:b→1, 2. This corresponds to the structure of *S. schottmülleri* isolated from pus involving bone and is the first instance in which a complete identification of the organism is offered.⁶

2085 Adelbert Road.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

WESTERN ELECTRIC 4C AUDIOMETER ACCEPTABLE

Manufacturer: The Western Electric Company, 300 Central Avenue, Kearny, N. J.

The Western Electric 4C Audiometer is a screening type instrument by which it is possible to test the hearing of as many as forty persons at one time. The firm states that the apparatus is essentially a phonograph to which has been added telephonic apparatus. The phonograph is of the spring motor type with a magnetic reproducer. The magnetic reproducer picks up the vibrations originated by the record and transforms them into electrical vibrations, which are conveyed to a telephone head-set and the person or persons under examination hear the sound waves as if by telephone. All the necessary electrical energy is developed in the magnetic reproducer.

Intensity of the speech sounds heard on the double faced specially made records decreases in small steps from a maximum to a minimum intensity; this process occurs four times in playing each side of the record. The first two series of numbers on each face are spoken in a woman's voice and the second two in a man's voice. Each decreasing series is composed of different numbers. The same rate of intensity attenuation is maintained in all eight series. Of the two records provided, one uses two digit numbers and is generally used for classes below the fifth grade; the other, with three digit numbers, is generally used for the fifth grade and above.

The individual being examined writes the numbers heard on a special recording sheet. A master sheet provided makes possible quick checking of the results.

An audiometer of this type cannot be judged in accordance with the requirements in the Council's adopted article "Minimum Requirements for Acceptable Audiometers." Since it is not a so-called pure tone audiometer, and the manufacturer does not claim it to be such, it is used only for screening purposes and not as a diagnostic instrument and is not accepted as such.

In investigating the instrument clinically a group of students entering college were tested for hearing loss in accordance with directions supplied by the manufacturer. The examination was a routine part of student health activities in a large university.

A group of men students (more than one hundred) was tested in the quietest room in the gymnasium building, and thirty of them were shown to have measurable hearing losses. When they were retested in a sound proofed room in the psychology laboratory, none of the thirty were found to have defective hearing. This points out the importance of having a very quiet room in which to conduct the tests.

The Council voted to accept the Western Electric 4C Audiometer for inclusion on its list of accepted devices as a device for assisting in testing the hearing of groups of individuals.

6. At the completion of this study, the abscess was again aspirated and the same organism was isolated.

Western Electric 4C Audiometer.

SATURDAY, APRIL 11, 1942

THE ATLANTIC CITY SESSION

Last week THE JOURNAL published a statement from Undersecretary of War Patterson urging continuation of plans for the annual session of the Association in Atlantic City. Discussion as to the desirability of proceeding with all the plans for the Atlantic City session led officials of the Association to communicate also with the Secretary of the Navy. A letter just received from Commander Edward A. Hayes, special assistant to Secretary Knox, states that Secretary Knox requested him to give the assurance that it is their hope that the proposed annual meeting of the American Medical Association will be a great success. To use the exact expression of Secretary Knox,

"There is no doubt that our defenses along the entire Atlantic Coast will be greatly improved by June and I regard any danger to guests of Atlantic City from that source as insignificant."

As has been stated previously, the special issue devoted to the plans for the Atlantic City session will be THE JOURNAL for May 2. The programs are complete. Special symposiums related to problems of current medical interest and to military medicine and the contribution of visitors from some of the Latin American countries are assured. All the exhibit space available in the Scientific Exhibit has long since been assigned and practically all the space in the Technical Exhibits has already been taken.

CONTROL OF DRUGS AND MEDICAL SUPPLIES

Some of the most complicated and difficult questions confronting various agencies concerned with the most efficient conduct of the war effort have been those concerned with making available to all war agencies proper amounts of essential drugs, chemicals and materials used in medical supplies and at the same time meeting essential civilian needs. Innumerable professional and commercial interests have been involved in these problems. As the problems have arisen, various agencies in the federal government have

been concerned with various aspects of these questions, so that correlation and coordination have been exceedingly difficult. Recently a preliminary conference was held by the Division of Medical Sciences of the National Research Council, to which a number of representatives of various agencies were called. A second conference, growing naturally from the first, was held in Washington April 3, at which definite action was taken leading to the establishment of a central committee to give consideration to each of the problems as they arise and thus to be able to advise all agencies as to basic facts necessary for the making of competent decisions.

The second conference was called largely as a result of a request received from Mr. J. S. Knowlson, director of the Division of Industry Operation of the War Production Board, who asked for the compilation of a list of drugs now scarce, an estimate as to scarce drugs essential to the national health, and the uses to which such drugs might be applied in order of their importance. It was recognized also that conditions change from day to day and certainly from month to month, so that a continuing body might be necessary and available for constant consultation.

In the conference called by the Division of Medical Sciences, representatives were present not only from the War Production Board, the Office of Price Administration, the Office of Defense Health and Welfare, the Office of Civilian Defense, the Federal Trade Commission, the Division of Medical Sciences of the National Research Council, the Army and Navy medical departments and the Office of Scientific Research and Development but also from the United States Pharmacopeia, the National Formulary, the American Drug Manufacturers Association and the American Medical Association. This conference adopted a motion reading:

That it be recommended to the Division of Medical Sciences of the National Research Council that a representative committee be established to consider and advise on problems of drug and medical supplies and on their distribution; that this committee include liaison representatives from all federal agencies now concerned with this subject; that the committee consider all problems related to the supply of essential drugs and medical supplies with a view to conservation, increased production or substitution and with a view toward coordination and correlation of effort for efficiency in the maintenance of the public health and satisfaction of military needs.

Subsequent to receipt of this action, the chairman of the Division of Medical Sciences, Dr. Lewis H. Weed, appointed a committee and requested each of the federal agencies concerned to designate a liaison representative who will sit constantly with the committee appointed. The Committee on Drugs and Medical Supplies includes:

Dr. Walter W. Palmer, New York, Chairman;
Vice Chairman, Council on Pharmacy and Chemistry,
American Medical Association;
Professor of Medicine, Columbia University Medical
School.

Dr. Perrin H. Long, Baltimore:

Chairman, Committee on Chemotherapeutic and Other Agents, Division of Medical Sciences, National Research Council;
Professor of Preventive Medicine, Johns Hopkins University Medical School;
Member, Committee of Revision, United States Pharmacopeia.

Dr. Ernest E. Irons, Chicago:

Formerly member, Council on Pharmacy and Chemistry, American Medical Association;
Secretary, Board of Trustees, American Medical Association;
Professor of Medicine, Rush Medical College.

Dr. Morris Fishbein, Chicago:

Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION;
Member, Council on Pharmacy and Chemistry, American Medical Association;
Member, Board of Trustees, United States Pharmacopeia;
Chairman, Committee on Information, Division of Medical Sciences, National Research Council.

Mr. J. G. Searle, Chicago:

President, American Drug Manufacturers Association;
President, G. D. Searle & Company.

Mr. George W. Merck, Rahway, N. J.:

President, Merck & Company, Inc.

Dr. E. F. Kelly, Washington, D. C.:

Chairman, Board of Trustees, United States Pharmacopeia;
Secretary, American Pharmaceutical Association.

Dr. O. H. Perry Pepper, Philadelphia:

Chairman, Committee on Medicine, Division of Medical Sciences, National Research Council, ex officio.

Dr. Evarts Graham, St. Louis:

Chairman, Committee on Surgery, Division of Medical Sciences, National Research Council, ex officio.

The committee proposes to establish subcommittees familiar with the essential information that will be required regarding available supplies of various drugs and medical materials and the means of conserving such materials, of substituting for them and of increasing production as the needs arise.

THE LONGEVITY OF PHYSICIANS

Physicians always advise their patients how to live longer and better; they themselves often die prematurely of preventable or at least postponable causes. The prevalence of deaths from heart disease, particularly coronary disease, among physicians at relatively early ages has in recent years increased sharply. Coronary disease has come to be known among physicians as "doctors' disease." Doctors favor health supervision without waiting for illness to appear. The National Health Council and the American Medical Association in 1922 declared in favor of periodic health examinations of apparently healthy persons. The American Medical Association has published a manual¹ and a blank² in the hope of stimulating medical interest in

periodic health examinations and several pamphlets³ intended to interpret the idea to the layman. Nevertheless, except for insurance company and industrial periodic examinations, the idea has not become popular.

A new development is the Committee on Longevity, Class of 1900, College of Physicians and Surgeons, New York, which has organized for the purpose of prolonging the lives and improving the health of the one hundred surviving members of the class, which originally numbered one hundred and seventy-five graduates. Already the idea has received much publicity through editorial comments in New York papers. Superficially amusing, but basically significant, is this comment from an editorial in the New York Sun:⁴

Laymen whom middle age prompts to think of such things are bound to be interested in the work of the Longevity Committee set up by the Class of 1900 of Columbia College of Physicians and Surgeons. These doctors should be able, if anybody can, to propagate the art of collective good health. Laymen will note with an understanding smile, however, one of the problems the Longevity Committee regularly meets as it conducts a monthly study of reports on physical examinations of the members. It finds that a good many doctors have this much in common with a good many laymen: they neglect their periodic examinations or delay in taking treatment.

If these physicians can stimulate others they may succeed in awakening a more lively interest among practicing physicians in periodic health examinations. At present medical and lay apathy in virtually equal parts explain the failure of the American people to adopt the sound and sensible idea of periodic health examinations as a means toward better and longer life.

Current Comment

PERSONNEL FOR THE ARMY AND NAVY MEDICAL DEPARTMENTS

The Procurement and Assignment Service for Physicians, Dentists and Veterinarians has been seriously engaged in clearing the names of physicians, dentists and veterinarians who have volunteered for service with the Army and Navy medical departments or with various other federal agencies. The tremendous demands made on the government printing office have somewhat delayed the printing of the enrolment form and questionnaire. The continuing demand for physicians makes it desirable therefore that physicians under 37 years of age continue to apply for enlistment in the Army and Navy medical departments.

The immediate needs of the Army and Navy medical departments and of the Air Force, as stated in previous issues of THE JOURNAL, will demand during the year 1942 approximately fifteen thousand or sixteen thousand additional physicians. Those now ready to make application need not delay, therefore, in submitting their names at once. Under the heading of Medicine and the War in this issue of THE JOURNAL appears an author-

1. Periodic Health Examination: A Manual for Physicians, Chicago, American Medical Association, 25 cents.

2. Periodic Health Examination Blanks, Chicago, American Medical Association, single copies 5 cents.

3. Height-Weight Table for Men and Women, Chicago, American Medical Association, 10 cents. What Is A Health Examination Anyway? by Haven Emerson, 10 cents. If I Keep My Health, by W. W. Bauer, 5 cents. That Annual Check-Up, by A. H. Aaron, 10 cents.

4. New York Sun, July 9, 1941.

ized statement by Rear Admiral Ross T. McIntire, Surgeon General of the United States Navy, indicating how physicians who wish to apply for commissions in the Navy may take action in that regard.

THE DISTINGUISHED SERVICE MEDAL

The Distinguished Service Medal of the American Medical Association will be presented for the fifth time at the Opening General Meeting during the annual session of the Association in Atlantic City, June 9. This medal was awarded, for the first time, in 1938 to Dr. Rudolph Matas of New Orleans, in 1939 to Dr. James B. Herrick of Chicago, in 1940 to Dr. Chevalier Jackson of Philadelphia and last year to Dr. James Ewing of New York. This award has come to be recognized as one of the most distinguished honors within the gift of the American Medical Association. The method of selection of the recipient of the Distinguished Service Medal is specifically defined in the By-Laws of the Association. Any Fellow of the Association may submit nominations, which should be sent, together with a record of the scientific services of the nominees, to the chairman of the Committee on Distinguished Service Award, Dr. A. A. Walker, 2250 Highland Avenue, Birmingham, Ala., or to the Secretary of the Association at 535 North Dearborn Street, Chicago. Of all nominations received by the committee, five are submitted to the Board of Trustees of the Association, from which the Board selects three to be submitted to the House of Delegates at its first meeting at the time of the annual session. Immediately on submission of the nominations by the Board of Trustees, the House of Delegates by official vote selects the recipient of the honor, to whom the Distinguished Service Medal is presented at the Opening General Meeting on the evening of the following day. An extended list of distinguished physicians nominated for this award will enable the Committee, the Board of Trustees and the House of Delegates, all of whom participate in the selection, to determine for 1942 a recipient of distinction, whose nomination will reflect favorably on himself and on the Association.

USELESS TANK TO BECOME USEFUL TANKS

At last the Cunningham tank is to serve some useful purpose. An Associated Press dispatch datelined Cleveland, March 31, states that this "giant shell ball . . . is being dismantled and its 1,000 tons of metal will go to the mills as scrap." The tank here referred to was originally constructed some thirteen years ago by the late Dr. Orval J. Cunningham of Kansas City, Mo., for the purpose of instituting his preposterous pressure treatment for diabetes, pernicious anemia and carcinoma. The million dollars required to build it was supplied largely by the industrialist Timken, manufacturer of bearings. Why do people of great wealth who are unacquainted with scientific fact and apparently unwilling to consult scientific authority so frequently support strange notions in the field of medical care? THE JOURNAL for May 5, 1928 carried a two and a

half page report of all the details connected with the method of treatment. "To explain his alleged results," said THE JOURNAL, "Dr. Cunningham advances a thesis that is altogether without scientific proof." It added "Under the circumstances, is it to-be wondered at if the medical profession looks askance at the 'tank treatment' and intimates that it seems tinctured much more strongly with economics than with scientific medicine?" Operated for several years on the unproved Cunningham thesis, it was noted in *Time* for Oct. 8, 1934 that

James Henry Rand Jr., chairman-president of Remington-Rand (office equipment), had sufficient faith to entrust Mrs. Rand to Dr. Cunningham's aerotherapeutics. And their son James Henry Rand III, onetime University of Virginia medical student, had sufficient faith to understudy Dr. Cunningham for the past seven years. Last week young Mr. Rand bought Dr. Cunningham's sphere for \$500,000, will henceforth operate it with the help of Dr. Carl William Iuler, 36, as the Ohio Institute of Oxygen Therapy.

Thus another industrial fortune was involved in this enterprise, which in the ensuing six years since its original construction had not accumulated the slightest bit of evidence of scientific worth. Fortunately the armed services of the United States will be able to find better use for the metal than it seems to have served.

CLINICAL ESTIMATION OF BLOOD PRESSURE

The recorded level of blood pressure, in addition to individual fluctuation, is affected by numerous technical circumstances, such as the nature of the apparatus and whether the measurement is made by auscultation or by palpation. In a new study of the accuracy of blood pressure recordings, Ragan and Bordley¹ compared auscultatory pressure measurements with intra-arterial pressure measurements one hundred and thirty-eight times in 51 adult subjects. They found that the agreement between the auscultatory and intra-arterial measurements of systolic pressure was affected both by the size of the subject's arm and by the contour of the pulse wave. They concluded, therefore, that the commonly employed clinical method of measuring blood pressure should not be considered a truly accurate procedure and that misinformation is particularly likely to be obtained in subjects with unusually large or unusually small arms. If the arm is small, the clinical estimate of the systolic pressure is likely to be too low; if the arm is large, the clinical estimate of both systolic and diastolic pressures is likely to be too high. The error in either direction may exceed 30 mm. of mercury. These workers believe, therefore, that statistical studies of the relationship between blood pressure and body weight should take into account the measurement of the circumference of the arm on the accuracy of the blood pressure measurements. These investigations add to the evidence already available that the clinical expression of blood pressures must be accepted conservatively and interpreted with caution.

1. Ragan, Charles, and Bordley, James, III: The Accuracy of Clinical Measurements of Arterial Blood Pressure, *Bull. Johns Hopkins Hosp.* 69: 504 (Dec.) 1941.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

METHOD OF PROCUREMENT OF MEDICAL OFFICERS FOR THE U. S. NAVAL RESERVE

Rear Admiral Ross T. McIntire, surgeon general of the Navy, has submitted the following information:

Recruitment of medical officers for the U. S. Naval Reserve has been transferred from the office of the commandants of the naval districts to the directors of naval officer procurement, located in the cities listed. A physician desiring to apply for appointment in the Medical Corps of the Naval Reserve should communicate directly with the director of naval officer procurement in the location nearest his place of residence. A communication addressed to the director should contain full information regarding date of birth, medical school from which graduated, and professional attainments since graduation. In this communication the prospective applicant should request a circular of information for persons desiring appointment in the U. S. Naval Reserve, and application forms for such appointment.

The Procurement and Assignment Service does not act as a recruiting agency for the U. S. Navy. Applications for appointment in the Medical Corps of the U. S. Naval Reserve are cleared through the Procurement and Assignment Service by the directors of naval officer procurement. The only purpose of clearing through this service is to determine which applicants hold civilian positions essential to national defense, to another governmental agency, and those considered essential

on teaching faculties of accredited medical and dental schools. Such individuals will not be offered commissions in the U. S. Naval Reserve.

If physicians fill out the new questionnaire blanks which are soon to be distributed by the Procurement and Assignment Service and indicate that they desire to apply for appointment in the U. S. Naval Reserve, their names will be submitted to the Bureau of Medicine and Surgery, which in turn will communicate with these physicians.

OFFICES OF NAVAL OFFICER PROCUREMENT

First Naval District, 150 Causeway Street, Boston.

Third Naval District, 33 Pine Street, New York.

Fourth Naval District, seventeenth floor, Widener Building, Philadelphia.

Fifth Naval District, Chevrolet Parts Building, Norfolk and Altamont streets, Richmond, Va.

Sixth Naval District, The Center, Marion Square, Charleston, S. C.

Seventh Naval District, Langford Building, 121 S.E. First Street, Miami, Fla.

Eighth Naval District, Louisiana Building, 217-227 Camp Street, New Orleans.

Ninth Naval District, Board of Trade Building, 141 West Jackson Boulevard, Chicago.

Eleventh Naval District, 850 Lilac Terrace, Los Angeles.

Twelfth Naval District, Federal Office Building, Civic Center, San Francisco.

Thirteenth Naval District, 117 Marion Street, Seattle.

Washington, D. C., 1320 G Street N.W.

THE BATTALION MEDICAL OFFICER

HAROLD R. CONN, M.D.,
Akron, Ohio

The battalion medical officer probably enjoys the most individualistic responsibility of any officer in the service. Where his colleagues attached to sorting stations, ambulance companies and evacuation hospitals have the advantage of contact and conference, he is likely to be alone at the time of greatest stress.

It is obligatory that the battalion surgeon be young, in perfect health and physically tough to withstand the rigors of active campaigning with his unit. He must master subjects foreign to his colleagues in the rear and, to mention a few, these include troop hygiene and sanitation, medical corps training and drill, map reading, orientation and something of tactics and the art of concealment. The training of his enlisted personnel is a task of paramount importance, and there are many other fields to explore, such as gas proofing. The selection of sheltered havens where battle casualties

may be protected, and the vital problem of feeding the wounded.

He may consider these exertions medical inactivity, but there will follow periods when all his skill will be required and the military routine will be less exacting than the professional requirements. These extraordinary demands will come during severe and sustained action and he must retain coolness and calmness and must show a near perfection of surgical judgment under the most adverse conditions. Surgical judgment is that indefinable but essential attribute compiled of just the right mixture of a stable nervous system, past surgical experience, common sense and an ever ready diagnostic ability. It seems a needless sacrifice; but wars are won by sending the best men to the front, for only the best possess the essential qualities necessary to insure victory.

The battalion medical officer's responsibilities make demands on his previous training but in surroundings and under conditions which exist nowhere in his past experience. He most certainly has never before been suddenly confronted with a half hundred or more

injuries running the gamut of head, chest, abdomen and extremities, nor has he ever before worked to the limit of his physical and mental capacities where all about him is chaos and confusion. True there is little in the routine but essential military training that fits him to meet this sudden and overwhelming activity, but experience can be simulated by military maneuvers and through special training from his regimental and division surgeons.

QUALIFICATIONS OF A FIRST LINE MEDICAL OFFICER

In fact, no greater duty rests on the division surgeon than to see that his first line officers are selected from men who show initiative and have had some civilian traumatic experience. They should be taught the routine and correct use of tourniquets and traction splints, the differentiation between traumatic and cerebral shock, and a profound appreciation of the effects of dehydration, exposure and hemorrhage on wounded men. In this training the time element should be stressed as all important. The rapid collection of wounded and their intelligent dispatch to the rear definitely determines the mortality rate of all except the trivial and the initially fatal injuries. Many problems will arise which never confront the physician in civilian practice, where the ever ready and fast ambulance delivers the casualty to the hospital receiving room usually within a matter of minutes, not hours, as may be the fact in war.

There exists the notion among young medical graduates that an appointment to operative surgical teams or to base hospitals offers opportunities to gain vast experience in chosen specialties, whereas being assigned as a battalion medical officer is an atrophy of previous education and is absurdly wrong.

With a few individual exceptions, the surgery in World War I taught the physician but little. As a member of an operating team he found that the injuries differed greatly from those seen in civilian life, and the technic of débridement (operative cleaning of the wound) was destructive rather than constructive. There was, moreover, no opportunity to observe the end results of operations done. In base hospitals the surgery was and will be done by a few men, and the junior officer will act as the equivalent of a house officer in a well organized civilian institution. Finally, between the surgical units operating behind the field of battle and the combat battalion there is little or nothing in the way of practical civilian medical experience to be acquired.

THE REAL TEST OF SKILL: BORDERLINE CASES

The battalion officer, on the contrary, after a period of military training may some day expect to find himself confronted with a number of injuries which would disorganize the largest civilian hospital in the United States. He may anticipate that in a relatively minor engagement 10 per cent of his battalion will be wounded. Considering the total casualties, one half will represent trivial and initially fatal wounds while the remaining half, or 50 per cent, will present the real test of skill. The mortality rate of this last group will be positively influenced by the ability, resourcefulness and courage of the medical officer.

It seems unnecessary to call attention to the fact that moribund patients should not be evacuated from the battalion aid station, yet this instruction had to be repeated again and again to the vast majority of bat-

talion surgeons during their early weeks of real action in the last war. As physicians all of us have been trained not to usurp the powers of Providence but to attempt to save every patient against impossible odds and to keep trying until life is fully and completely lost. This principle cannot entirely endure on the battlefield. Even to the inexperienced medical officer it must be obvious that he will be confronted simultaneously with hopelessly wounded and with cases in which reasonably prompt treatment and evacuation will result in recovery. He must learn under the trying conditions of active combat to recognize promptly the fatally injured and enulate the calm impartiality shown by the judiciary when they pass sentence by refusing to clutter his limited evacuation facilities with the doomed. It is platitudinous to state that, no matter how good the surgical facilities and personnel may be in the rear, they cannot save mortally wounded and dead men. The borderline cases present the real test of ability. Many of these may be saved by proper deshocking, either prompt mobilization or immobilization awaiting reaction, all depending on the wound and the response to initial diagnosis and treatment.

In a lifetime of emergency surgery the physician will probably not be called on to make the decisions which were demanded daily of the battalion surgeon during such offensives as the Meuse Argonne. Questions as to whether to give more morphine or to withhold it, to continue deshocking by external heat and posture or attempt to rush the patient to a hospital, to loosen the tourniquet at the risk of death or to leave it tight and sacrifice a limb, to attempt to separate cerebral shock from traumatic shock, and to estimate the degree which cold, fright, dehydration, and exposure aggravated wounds were presented at times by the minute.

These are not flights of fancy but the cold reality which confronts the battalion surgeon hidden in a poorly lighted dugout or in a shell hole under fire in the dead of night without adequate help, with some of his own stretcher bearers wounded and with the field around him still covered with badly wounded but unrecovered men. There will be no blood pressure readings, no x-ray examinations and no pulse and respiration charts to help him. It should take but little imagination for the young officer to picture for himself the difference between this scene and the one in the hospital in which he trained, where an occasional casualty was brought in, where he had an abundance of professional assistance, superb nursing care, electric lights and blood transfusion available within ten or fifteen minutes after injury. The officer who feels that his professional talent will be wasted as a battalion surgeon simply hasn't been there.

It should be reemphasized that he must exercise not only coolness and good sense but shrewd diagnostic acumen under the most adverse conditions without the benefit of counsel and often after twenty-four hours or more of constant duty.

THE BUILDING OF MORALE

The morale of any battalion is very positively influenced by the ability and the élan of its medical personnel. Combat troops, however courageous, react splendidly to the knowledge that if wounded and helpless on the field they will somehow be recovered by the medical corps and will receive prompt, adequate and competent care. The outstanding records of many units can be partially credited to the courage and resourcefulness

of their supporting medical detachments. There is no place in either civilian or military professional activity where gratitude and devotion are so generously given as to a real doctor in action with combat troops.

After recovery and segregation in the battalion aid station or the collecting station the most common question asked the medical officer by the wounded is "How seriously am I hit?" or "Am I going to get well?" and the reaction on the part of the patient to a cheerful and reassuring response is one of the amazing phenomena of war wounds. It is second only to the dramatic reaction made by wounded men when placed in deshocking cabinets and external heat applied.

Every variety of injury needs special attention, but it should be recalled that during the first two years of the last war the mortality rate, not taking into account the amputation rate, of compound fractures of the femur was 83 per cent, a ghastly total which exceeded gunshot wounds of the head, the chest or the abdomen. When in 1916 the use of traction splints in the field as advocated by Sir Robert Jones was made a military order, the mortality of compound fractures of the femur was reduced to 27 per cent. The reduction was not so spectacular in the other compound fractures but it was sufficient to make it a military offense to ignore the dictum "Splint 'em where they fall."

ENLISTED MEN BECOME ADMINISTRATIVE CORPS OFFICERS

Two hundred and twenty-four enlisted men of the medical department of the Army became second lieutenants, March 28, when they graduated from the officer candidate course at the Medical Field Service School, Carlisle Barracks, Pa., following a course of instruction. These men were selected to attend the school by reason of their excellent military records. Forty-nine of the candidates were regular army enlisted men, nineteen were from the National Guard and one hundred and fifty-seven entered the army through Selective Service. The majority of them had only one year or less of service, thirty-one had had two years and thirty-one others three years of service. One hundred and twenty-six members of the class had college degrees, eighteen were pharmacists and seven were lawyers. The new officers came from thirty-six different states. The diplomas were presented by Brig. Gen. Addison D. Davis, Assistant Surgeon General of the Army and commandant of the Medical Field Service School. The oath of office was administered by Major Thomas G. Hester, one of the senior officers of the medical administrative corps.

THE HOARDING OF FIRST AID MATERIALS

Director James M. Landis of the Office of Civilian Defense, Washington, D. C., has announced that a wave of hoarding of first aid material is sweeping the country and threatens to produce a serious shortage of surgical gauze, bandages and other essentials required by the army and the Emergency Medical Service of the Office of Civilian Defense. Millions of first aid kits, he said, are being installed in countless places where there is practically no likelihood that they will ever be used. This unlimited purchasing of first aid material is based on a wrong conception of air raid casualties. Dr. George Baehr, chief of the Office of Civilian Defense Medical Division, said. These casualties are usually of such severity that only trained emergency medical field units are competent to attend the injured at the site of the accident. Emergency medical field units composed of doctors, nurses and trained auxiliaries have been established in every community likely to be bombed, especially on

THE DOCTOR IN ACTION

It is not the intent here to discuss the intriguing differentiation in the treatments of exposure, hemorrhage, acidosis and shock, for books have been written about the cause, symptoms and treatment of each individually. The battle casualty usually presents a combination of all of them, but the battalion surgeon will be amazed at the reactions of apparently desperately injured young soldiers to reassurance, traction splinting, morphine, external heat and hot fluids internally.

The treatment of infections and the chemotherapy of wounds by use of the sulfonamides likewise present special problems in instruction.

Once in action the days of paper forms, sanitary inspections and foot work are forgotten and the battalion officer becomes what he has studied and worked and hoped to be: a doctor in the full sense of the word. Among medical veterans the expression is common that if they go again they want to serve with troops and it is not only the excitement but the actual professional responsibility which inspires them.

Possibly good battalion surgeons are born or just happen, but certainly many can and must be made; for the whole medical organization behind them is dependent on their ability, while ahead of them the soldier places his trust and his life in their hands.

1144 East Market Street.

our coasts, and these units are promptly available in all parts of the community, day and night. Air raid wardens will not be expected to care for the wounded in the event of air raids, but, because of the present misunderstanding, tens of thousands of air raid wardens are stocking up on first aid material and urging every one in their zone to do so. Many households are duplicating the materials already in their medicine cabinets which would be of little value for the major crushing injuries which are characteristic of air raids. A small kit has been designed which contains a few large shell dressings and can be worn on a belt for an air raid warden or a trained stretcher bearer. Mr. Landis said that the rapidly increasing wastage of gauze bandages and other first aid material is reaching alarming proportions.

ONE MILLION BLOOD DONORS REQUIRED

The program of the American Red Cross for supplying blood plasma to the armed forces has entered its second year of operation, 30,477 blood donations being reported for the first two weeks in March by Red Cross chapters maintaining donor centers. Inaugurated in February 1941 at the request of the surgeon generals of the Army and Navy, this project has expanded as rapidly as laboratory facilities to process plasma have become available. Donor centers are now operating in eighteen cities. Shortly after beginning the project, the Red Cross was requested to deliver 380,000 units of plasma by July 1942. For the year beginning July 1, 1942 the Army and Navy have requested the Red Cross to obtain an additional 550,000 units, making a minimum total of 930,000 units. To provide this total will require somewhat in excess of a million donors. According to Dr. G. Canby Robinson, director of the Red Cross Blood Donor Service, the present rate of donations will have to be maintained without letup and may even have to be increased. Red Cross blood donor centers are now in operation in New York, Philadelphia, Baltimore, Buffalo, Rochester, N. Y., Indianapolis, Detroit, Pittsburgh, St. Louis, Boston, Milwaukee, Cleveland, Chicago, San Francisco, Los Angeles, Cincinnati, Washington, D. C., and Brooklyn. Seven commercial laboratories have contracts with the government for processing plasma on a cost basis. The total number of donations during the first year of operations aggregated 82,857. The value of

blood plasma in the treatment of burns and wounds and in combating shock was amply demonstrated at Pearl Harbor. Surgeons on duty there state that many lives were saved through the use of plasma supplied by the local medical society, the American Red Cross and other agencies.

INSTRUCTION IN CHEMICAL WARFARE

A series of four day intensive courses for teaching the medical aspects of chemical warfare to qualified physicians is to be given at the University of Cincinnati College of Medicine, which was selected by the Office of Civilian Defense, Washington, D. C. In the first group which took this course, beginning February 23, there were about thirty physicians from New England, New York and the Middle Atlantic states. Another course was started on April 6 for physicians from other parts of the country. The course was organized by Dr. Leon Goldman of the department of dermatology and Dr. Robert A. Kchoe, director of the Kettering Laboratory.

A school for gas defense to train experts in the field of poisonous gases will be established at the University of Buffalo (N. Y.). It is being inaugurated at the request of the Erie County Defense Council, whose chairman, Erie M. Wheeler, has appointed Dr. Howard W. Post, assistant professor of chemistry at the university, to organize the course of instruction. Fifty teachers from high schools of Erie County will take the course to prepare themselves for instructing civilians in their communities. Dr. Post says that the course will consist of three Saturday afternoon and one evening classes with a total of twelve hours of instruction to be provided by seven instructors.

SERVICE CLUBS FOR AUSTRALIA

The American Red Cross has announced that a staff of eight welfare workers with the American troops in Australia will set up Red Cross service clubs to provide recreation, sleeping quarters and canteen service for men on leave in at least three Australian cities. In charge of each of the clubs will be a prominent American man and woman, a social worker and volunteers from American residents in Australia. Charles Gamble, American business man long resident in Australia, will be American Red Cross delegate, with headquarters in Melbourne, and director of all activities; Irving Williams of the Washington national staff will be field supervisor of the Red Cross Military and Naval Welfare Service in all military stations, and Albert Scott, formerly with the Near East Foundation, will be recreational supervisor. The Red Cross also said that three million surgical dressings made by women volunteers have been shipped to the Australian Red Cross for use in Australian hospitals.

ALLOCATION OF EQUIPMENT FOR CIVILIAN DEFENSE

The first allocation of fire fighting equipment, gas masks, stretchers and cots under the recent \$100,000,000 Congressional appropriation for civilian defense will be made principally to certain cities within 300 mile coastal strips which are regarded as "target areas," a memorandum of plans released by James M. Landis, director of the Office of Civilian Defense, states. Communities will be selected largely on the basis of priorities established by the War and Navy departments. Three basic considerations will be used in determining priorities among communities: likelihood of attack, vulnerability and importance of war production of manufacturing plants in the communities. In urging communities not to send requests for requisitions for supplies to the headquarters of the Office of Civilian Defense in Washington, Mr. Landis says "Allocations of protective supplies must and will be made according to plans arrived at in cooperation with the military experts of the War Department. Under the law we cannot make allocation on any other basis and we will be unable to give consideration to the requests of individual localities at variance with such a plan."

Tentative allotment of equipment for medical teams and casualty stations will be made on the basis of (a) one team

for each 5,000 of population, (b) one casualty station for each two medical teams, stretchers on the basis of four for each 5,000 of population, cots on the basis of twelve for each 5,000 of population, first aid belts on the basis of nine for each 5,000 of population, and identification tags for medical kits on the basis of one book of twenty tags for each 5,000 of population.

Procurement of all the equipment and supplies will be by appropriate agencies of the War Department.

REPORTING OF REGISTRANTS WITH VENEREAL DISEASE

The following memorandum has been received from the City of New York Department of Health:

Current Selective Service medical and serologic examinations emphasize the value to the practitioner of prompt compliance with the venereal disease provisions of the sanitary code. All registrants found infected with syphilis, gonorrhea, chancroid or lymphogranuloma venereum are referred by the Selective Service administration to the health department for further consideration. Where the registrant is under medical care by his physician and has been properly reported, no further action is taken. Where men are not under medical care the need for rehabilitation, as well as for public health control of communicable disease, leads to intensive follow-up procedure to place all infected registrants under treatment. This follow-up is made by the health department by arrangement with the Selective Service.

Each physician should review his venereal disease cases and submit the required case report (417V) to minimize the possibility of inconvenience to him and particularly to his patients eligible for military service. A supply of the required forms and the regulations for reporting may be secured by application to the Bureau of Social Hygiene, Room 328, 125 Worth Street, New York City, or by telephoning Worth 2-6900, extension 252.

REHABILITATION PROGRAM

The Baltimore City Medical Society sponsored a meeting at Osler Hall, Baltimore, March 13, which was entirely devoted to the subject of the physical rehabilitation of Selective Service registrants. Brig. Gen. Lewis B. Hershey, National Director of Selective Service, discussed "The Program of Selective Service in the Rehabilitation of Registrants"; Col. Leonard G. Rowntree, Chief, Medical Division, National Selective Service Headquarters, "Medical Aspects of Rehabilitation"; Col. Henry C. Stanwood, State Director, Maryland Selective Service System, "Administrative Responsibilities of Rehabilitation," and Lieut. Col. Amos R. Koontz, State Medical Director, Maryland Selective Service System, "Brief Outline of the Maryland Rehabilitation Plan."

Maryland has been selected by the National Selective Service System Headquarters as the first state in which to try out the physical rehabilitation plan announced by the President. The plan involves the correction of remediable defects which disqualify registrants for general military service. The correction of defects is to be done by designated physicians and dentists at government expense.

THE BOTKIN HOSPITAL IN MOSCOW RECENTLY BOMBED

The largest medical unit in the Soviet Union, the Botkin Hospital in Moscow, was severely bombed during the German raids several months ago, but not 1 patient was killed, according to the Moscow radio correspondent of the New York Times. The Botkin Hospital had two thousand, three hundred and fifty beds available to war wounded, and until the Germans retreated from Moscow it was practically a front line hospital. At present the medical center is acting as a base hospital and even is resuming medical courses for the training of field surgeons. The Times correspondent said that medical supplies from the United States had been arriving and that a considerable proportion of the material from the Allies was going to new military hospitals being established elsewhere in the Soviet Union.

AMERICANS IN CANADIAN ARMED FORCES

Americans serving with the Canadian armed forces will be given an opportunity to enlist in the U. S. Army or Navy under an agreement with Canada, the State Department has announced. About fifteen thousand Americans are now in the Canadian services. The agreement provides that Canadian authorities, not later than April 6, shall inform all Americans who have lost their citizenship by taking an oath of allegiance on enlistment in the Canadian armed forces that they may regain their citizenship and enlist in the American services. April 20 was set as the limit for transfer applications.

SUPERINTENDENT OF NURSES PROMOTED TO COLONEL

The Superintendent of the Army Nurse Corps, Mrs. Julia O. Flikke, was promoted on March 14 to the grade of Colonel and the Assistant Superintendent of the Nurse Corps, Florence A. Blanchfield, to Lieutenant Colonel, for the duration of the war. Colonel Flikke, a native of Wisconsin, entered the school of nursing of Augustana Hospital, Chicago, in 1912, took postgraduate work at Columbia University, joined the Army Nurse Corps in 1917 and soon after was ordered overseas. She was appointed superintendent of the Army Nurse Corps with the relative rank of major in 1937. Colonel Flikke has served at various army stations, including the Philippines and Tientsin, China. Lieutenant Colonel Blanchfield is a native of West Virginia and graduated in nursing from the Southside Hospital in Pittsburgh, entering the Army Nurse Corps in 1917. She did postgraduate work at Johns Hopkins Hospital, Baltimore, and has served in France, China and the Philippines.

GEN. FREDERICK RUSSELL RECEIVES THE SNOW AWARD

Brig. Gen. Frederick F. Russell, U. S. Army Medical Reserve Corps, received the William Freeman Snow Award for distinguished service to humanity in the social hygiene field at the annual meeting of the American Social Hygiene Association in Boston, February 3. General Russell was for many years a member of the medical corps of the Army. He played a leading role in introducing antityphoid vaccination in the Army, carrying on this work at the time he taught bacteriology in the Army Medical School. The Snow Award was made in recognition of General Russell's work in organizing the syphilis and gonorrhea control program in the Army in the first world war, which it is said has become the basis of the present army program in this field. The two former recipients of this award were Gen. John J. Pershing and Surg. Gen. Thomas Parran of the U. S. Public Health Service.

THE WELLCOME MEDAL AND CASH AWARD

The Association of Military Surgeons of the United States announces the competition for 1942 for the Sir Henry Wellcome medal and cash prize of \$500 for the best paper on "Measures of Preventive Medicine Recommended by the Federal Medical Services to Insure the Maximum Improvement of the Selectee of 1961 over Him of 1941." The competition is open to all medical department officers of the Army, Navy, Public Health Service, organized militia, U. S. Veterans Administration, U. S. volunteers and those in the reserves, commissioned medical officers of foreign military services and all members of the association, except that no one person shall be awarded a prize more than once in these prize competitions. Competitors must send five copies of their paper unsigned by their true name but identified by a device or nom de plume to the Secretary of the Association of Military Surgeons of the U. S., Army Medical Museum, Washington, D. C., to arrive not later than Aug. 31, 1942 and accompanied by a sealed envelop marked on the outside with the fictitious name or device assumed by the writer and enclosing his true name, title and address. The essays must have a minimum of three thousand words and must not exceed ten thousand words.

ONE WEEK INSTITUTES FOR NURSES

Under the sponsorship of the American Red Cross, the Michigan Department of Health, the Michigan State Nurses Association and the W. K. Kellogg Foundation, one week institutes are being given at Clear Lake Camp near Battle Creek, Mich., to provide an opportunity for Michigan nurses to brush up on their technic for teaching home nursing classes in connection with the civilian defense program. The first of the institutes was held the week of March 9, the second began March 16, and others will follow. The Kellogg Foundation provides meals and lodging for nurses in attendance.

BALTIMORE'S DECONTAMINATION CORPS

"Sniff" sets will be used to teach one hundred and sixty-one employees of the Bureau of Street Cleaning of Baltimore how to recognize war gases as a part of their instruction in methods of gas decontamination, the Baltimore Sun reports. In the group there will also be seventy-five chemists and one hundred and forty-two additional citizens. These will comprise the city's decontamination corps. Decontamination of streets and lawns and first aid for victims of war chemicals will be taught those taking the course.

BLOOD DONOR DAYS

The facilities of the Wayne University Student Health Service, Detroit, beginning February 16, were turned over to a Red Cross mobile unit for the receiving of contributions of blood for as many days as are necessary to care for the volunteers. Two hundred students and faculty contributions may be accommodated by these facilities each day. The student chairman of the project is Louis McGuiness.

TEACHERS OF AIR RAID WARDENS

The Civilian Defense Institute at Wayne University, Detroit, which was organized last month, trains school teachers and industrial leaders to be teachers of air raid wardens. A class of one hundred and sixty graduated on March 12, and more than two hundred and fifty persons are studying defense organization, blackout, air raid precautions, elementary camouflage, and fire and gas defense.

CAPTAIN STEPHENSON RETURNS FROM LONDON

Capt. Charles S. Stephenson, Medical Corps, U. S. Navy, recently attached to the American embassy in London, England, addressed a meeting of the Caduceus Post of the American Legion, New York City, at the Seventh Regiment Armory, March 25, on "Military Medical Observations in England."

DR. TURNER ON DUTY IN SURGEON GENERAL'S OFFICE

Lieut. Col. Thomas B. Turner, medical reserve corps, U. S. Army, professor of bacteriology at Johns Hopkins School of Hygiene and Public Health, has been ordered to active duty in the Surgeon General's Office, Washington, D. C., as chief of the subdivision of venereal disease control.

COLONEL HILLMAN PROMOTED TO BRIGADIER GENERAL

The President sent to the Senate, January 28, for confirmation the promotion to the temporary grade of brigadier general of Col. Charles C. Hillman, M. C., U. S. Army. Colonel Hillman, who has been in charge of the professional service division of the Office of the Surgeon General, will continue his tour of duty in that office.

DR. LEE ADDRESSES ARMY OFFICERS

Dr. Roger I. Lee, Boston, member of the Board of Trustees of the American Medical Association, addressed the medical department officers in Washington, D. C., February 16, at the Army Medical Center on "The Significance and Course of Borderline Abnormalities of Blood Pressure."

ORGANIZATION SECTION

OFFICIAL NOTES

THE ATLANTIC CITY SESSION

Hotel Reservations

Fellows of the Scientific Assembly of the American Medical Association who expect to attend the annual session of the Association in Atlantic City, June 8-12, are urged to make

their hotel reservations at the earliest possible time. For such reservations, please send your first, second and third choice for a hotel reservation to Dr. V. Earl Johnson, Chairman of the Hotel Committee, 16 Central Pier, Atlantic City, N. J., in accordance with the information contained on advertising page 48 of this issue of *THE JOURNAL*.

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION

New York

Bills Introduced.—S. 1156, to amend the workmen's compensation law, proposes to eliminate the provision of the present law authorizing an employee or carrier to select and pay for a physician to participate in an examination of the injured employee. S. 1217 and A. 1593, to amend the labor law, propose to limit the hours of employment of an ambulance chauffeur or driver in a private hospital or other private institution to not more than eight hours a day or forty-eight hours a week except in event of an extreme emergency. S. 1271 and A. 1613, to amend the public health law, propose to authorize the commissioner to establish temporary health districts, whenever the protection of the public health so requires, and to promulgate temporary health regulations to be effective in such districts. S. 1325 and A. 1668, to amend the education law, propose to make it unlawful for any corporation, joint stock association, company, association or individual doing business under a certificate of trade name to practice podiatry. A. 1386, to amend the general business law, provides for the regulation of nurses registries throughout the state. The term nurses registry means the business of conducting a registry, office or other place for the purpose of counseling, offering, procuring, promising or attempting to procure employment or engagements of any kind, for registered professional nurses, or for licensed practical nurses, or for dietitians, anesthetists, medical secretaries or medical technicians and for which a fee is exacted or charged. A. 1399, to amend the labor law, provides that, in cities having a population of over one million, ambulance drivers shall not be permitted to work more than eight hours a day or

more than forty-eight hours a week or more than six days a week except in case of certain specified emergencies endangering life or property. A. 1642, to amend the labor law, provides that unemployment compensation benefits shall not be denied to any person who has become incapacitated through illness and who had previously qualified for benefits. A. 1673, to amend the labor law, proposes that any employee, registered as totally unemployed, who is capable of employment at the time of registration, and subsequently becomes sick, shall not be prevented from obtaining benefits under the unemployment compensation act due to inability to accept employment.

Bill Passed.—The following bill has passed the assembly: A. 964, to amend the insurance law, proposes to authorize the writing of insurance against an obligation of the insurer to pay medical, hospital, surgical and funeral benefits to injured persons, irrespective of legal liability of the insured.

Rhode Island

Bills Introduced.—H. 833 proposes to repeal the existing law relating to the licensing and regulation of the practice of veterinary medicine, surgery and dentistry. H. 836, to amend the law relating to the licensing and regulation of hair dressers and cosmetic therapists, proposes, among other things, that "hair-dresser and cosmetician" shall include a person who, by the use of the hands or appliances or of cosmetic preparations, antiseptics, tonics, lotions, creams, powders, oils or clays, engages, with or without compensation, in massaging, cleansing, stimulating, manipulating, exercising or beautifying or in doing similar work on the neck, face or arms or who removes superfluous hair from the body of any female person.

WOMAN'S AUXILIARY

California

Capt. Samuel Ross of the Fresno Air Base was guest speaker at a recent meeting of the Fresno County medical auxiliary at the University-Sequoia Club. On January 5, the group met to discuss the part which doctors' wives might play in the defense program. It was decided that a complete file of the qualifications of members and a call list be kept. Entertainment was furnished by a chorus made up of members of the evening adult education classes of Fresno High School.

Georgia

About 500 health leaders of Fulton, DeKalb and Rockdale counties attended the health education meeting sponsored by the Woman's Auxiliary to the Fulton County Medical Society recently at the Crawford W. Long Nurses' Home in Atlanta. Mrs. Jeff Richardson, chairman of health films, explained how these films can be obtained by any one interested. The new sound films and film projectors in each district are owned by the Medical Association of Georgia. Dr. W. A. Selman, counselor for the Fifth District, talked on what the association hopes to accomplish for the health of Georgians by showing the films.

The Woman's Auxiliary to the Fulton County Medical Society met recently in Atlanta with Mrs. Murdock Egan, president, presiding. Mrs. Harry Rogers, chairman of Research in Romance of Medicine, had charge of the program, which featured a talk by Dr. Sterling Clairborne on vitamins. Mrs. Allen H. Bunce gave a report on the recent meeting of the Woman's Auxiliary to the Southern Medical Association, held in St. Louis.

New Jersey

At the January meeting of the Camden County auxiliary, the members voted to increase the annual dues from \$2 to \$3. Fifty defense stamp booklets, each containing one 25 cent stamp, were sold to members at this meeting. On January 19 the auxiliary attended a "Friendship Dinner" in Camden given to encourage cooperation of the auxiliary with the women's clubs and other organizations.

The Tuberculosis Hospital at the medical center in Jersey City entertained thirty members of the Woman's Auxiliary to the Hudson County Medical Society in January. The auxiliary decided to buy a \$1,000 defense bond. Pamphlets were distributed to each member to promote individual purchase of defense bonds and stamps.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

State Medical Meeting.—The Arkansas Medical Society will hold its sixty-seventh annual meeting in Hot Springs National Park, April 27-29, under the presidency of Dr. H. Fay H. Jones, Little Rock. Sessions will be held at the Arlington Hotel. A public meeting will be held Monday evening. Out of state speakers at the scientific sessions will include:

Dr. Winthrop M. Phelps, Baltimore, The Problem of Cerebral Palsy and Its Relation to Rehabilitation and Public Health.
Dr. Walter S. McClellan, Saratoga Springs, N. Y., The Importance of Spas in Military and Civilian Defense Program.
Dr. William J. McMartin, Omaha, Goldblatt Kidney.
Dr. Lawrence T. Post, St. Louis, Aniseikonia.
Dr. Charles M. Wilhelmj, Omaha, The Etiology and Treatment of Traumatic Shock.
Mr. John M. Pratt, Chicago, National Physicians' Committee for the Extension of Medical Service.
Dr. Delmas K. Kitchen, Detroit, Sex Hormones: Physiology, Diagnosis, Therapy.

A memorial session will be held on Tuesday at the First Presbyterian Church.

CALIFORNIA

Industrial Accident Section.—The Industrial Accident Section of the Los Angeles County Medical Association observed the twentieth anniversary of its founding in March. The *Bulletin* of the Los Angeles County Medical Association recalls that in 1929 the group instituted an educational program to standardize the treatment of industrial casualties and began the publication of scientific papers for that purpose.

University President Honored.—A life fellowship in the Thomas A. Edison Foundation for the Advancement of Science and Education has been conferred on Robert Gordon Sproul, LL.D., Berkeley, president of the University of California, Science reports. The award is given to "only a few outstanding Americans in the fields of medicine, science, art and education, who have made some real contribution to human welfare." Dr. Sproul has been president at California since 1930. Until the recent appointment of Dr. Francis S. Smyth as dean of the University of California Medical School, San Francisco, Dr. Sproul had been acting dean.

CONNECTICUT

Dr. Meader to Direct Cancer Research.—Ralph G. Meader, Ph.D., assistant professor of anatomy, Yale University School of Medicine, New Haven, has been appointed assistant to the director of the Jane Coffin Childs Memorial Fund for Medical Research at Yale and will supervise the fund's activities during the absence of Lieut. Col. Stanhope Bayne-Jones, director, who has reported for duty in the Office of the Surgeon General, Washington, D. C. The Childs Memorial Fund was established at Yale in 1937 and is primarily concerned with cancer research.

Rehabilitation Clinics.—The state department of education, the state medical society and the Manufacturers Association of Connecticut are cooperating in a series of rehabilitation clinics for the purpose of employing physically handicapped persons in Connecticut factories. Groups of crippled and otherwise handicapped persons registered with the rehabilitation service of the department of education will be brought together in clinics at several points within the state, examined by a team of physicians provided by the state medical society and classified according to their occupational capabilities. Yale University is making available a staff of psychologists to administer aptitude and performance tests. The Manufacturers Association of New Haven County will be represented by a committee of employers who will aid in determining occupational fitness. A representative of the U. S. Employment Service for Connecticut will be present to facilitate referrals to employers. The applicants will then be interviewed by employment managers of Connecticut factories and placed in jobs they will be able to fill. New Haven was selected for a clinic area as an initial step. On March 15 an all day clinic was held for a minimum of twenty physically handicapped persons. Examinations were made by a group of specialists selected by the state medical society.

GEORGIA

State Medical Meeting in Augusta.—The Medical Association of Georgia will hold its annual meeting at the Bon Air Hotel, Augusta, April 28-May 1, under the presidency of Dr. Allen H. Bunce, Atlanta. The program will include symposiums on public health problems, psychoses and psychoneuroses, eye, ear, nose and throat problems and the roentgenologic problems of the gastrointestinal tract. Speakers include:

Dr. Charles W. Roberts, Atlanta, Human versus Material Values in Medical Practice.
Dr. Frank H. Lahey, Boston, Medical Problems: National, Economic and Scientific.
Dr. Thomas J. Collier, Atlanta, Crawford Williamson Long, 1815-1878.
Dr. Robert C. Major, Atlanta, Obliteration of Chronic Empyema Cavities.
Dr. Reuben M. Reiffer, Macon, Fungous Infections of the Skin.
Drs. Robert F. Norton and John T. McCall Jr., Rome, Treatment of Lung Abscess with Alcohol Intravenously.

The Abner Wellborn Calhoun Lecture will be delivered Wednesday by Dr. Perrin H. Long, Baltimore, professor of preventive medicine, Johns Hopkins University School of Medicine, Baltimore, on "Sulfonamide Therapy: Its Applications and Limitations."

IDAHO

Society News.—The Southwestern Idaho Medical Society was addressed in Boise, February 20, by Drs. Frank M. Sprague, Boise, on "Evaluation of Physical Fitness" and William W. Bauer, Director, Bureau of Health Education, American Medical Association, Chicago, "Medical Relationships to War Activities."—Dr. Dan C. McDougall discussed "Acrodynia or Pink Disease" before the Pocatello Medical Society, Pocatello, recently.

ILLINOIS

Public Health Conference.—The second annual public health conference of the Illinois Public Health Association will be held at the Hotel LaSalle, Chicago, April 20. One general session will be devoted to "Integration of Public Health and Civilian Defense." On Monday evening Dr. Roland R. Cross, state director of health of Illinois, will give an address on "Public Health in War Time" and Carl E. Buck, Dr.P.H., New York, of the American Public Health Association, "The Future of Public Health in Illinois." The luncheon session on Tuesday will be addressed by Dr. Morris Fishbein, Editor of THE JOURNAL, on "The Effect of the War on Public Health Personnel and Programs." There will be round table and panel discussions, one session for milk sanitarians and a joint bacteriology and sanitary engineering session.

CHICAGO

Lilly Prize Awarded to Biochemist.—The Eli Lilly prize of \$1,000 in biologic chemistry has been awarded to Earl A. Evans Jr., Ph.D., associate professor of biochemistry, University of Chicago, for his work which "revolutionizes thinking about the role of carbon dioxide in the animal body." Dr. Evans received his Ph.D. at Columbia University, New York, in 1936. He was assistant pharmacologist at the Johns Hopkins University School of Medicine, Baltimore, 1931-1932; assistant in endocrine research, University of Chicago, 1932-1934. He became instructor in biochemistry in 1937, assistant professor in 1939 and associate professor, July 1, 1941.

War Conference for Protection of Industrial Workers.—A war conference for the protection of workers in industrial plants was held at the Stevens Hotel, April 9-10, under the auspices of the Office of Civilian Defense of the Chicago Metropolitan Area in cooperation with the Chicago Association of Commerce and the Illinois Manufacturers' Association. The purpose of this meeting was to acquaint operators of factories, warehouses, stores and all other kinds of industrial plants with the problems of plant protection they are likely to meet under war conditions and to advise them of the kinds of internal organization they may set up in order to mesh properly with the Office of Civilian Defense organization in the metropolitan area. The following problems were discussed, among others: enemy attack by air raid or gas; sabotage, espionage and other fifth column activities; accidents, fire and other industrial hazards made acute by sustained peak production; emergency medical, hospitalization and medical services; emergency communications and guard organizations, and identification systems. Among the speakers were:

Mayor Edward J. Kelly, U. S. Coordinator of Civilian Defense, Chicago Metropolitan Area.
Sterling Morton, president, Illinois Manufacturers' Association.
Dr. Morris Fishbein, Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.
Dr. Herman N. Bundesen, president, Chicago Board of Health.
Dr. Harry E. Mock, Chairman of the War Relocation Authority Council, Committee on Industrial Health.
Bennett S. Chapple, Defense Coordinator, Carnegie-Illinois Steel Corporation.

MAINE

Cooperative Program for Blood Banks.—Fourteen hospitals in Maine are cooperating in the first integrated system of blood plasma banks for civilian protection in New England communities, according to the state medical journal. Under a plan drawn up by the faculty of Tufts College Medical School, Boston, communities will receive protection in proportion to the amount of blood they donate. Collection depots will be set up in each of the fourteen community hospitals which will forward the blood to the Central Maine General Hospital in Lewiston for extraction of the plasma. On its return the plasma will be stored in the local hospital for emergency use. The Lewiston plan provides for retention of about 10 per cent of the plasma at the regional center, which will be available for use in any community which suffers a major disaster. Local hospitals in turn may retain for one or two weeks several units of whole blood for use in direct transfusions and especially for immediate protection while first plasma supplies are being processed in Lewiston. Drs. Joelle C. Hiebert and Julius Gotlieb, medical superintendent and pathologist, respectively, of the Central Maine General Hospital, and William Dameshek, assistant professor of medicine at Tufts College Medical School and chief of the Blood Clinic at the New England Medical Center, are in charge of the program. The hospitals in the Lewiston network include:

Central Maine General Hospital, Lewiston
St. Mary's General Hospital, Lewiston
Augusta General Hospital
Bath Memorial Hospital
Brunswick Hospital
Canden Community Hospital
Knox County General Hospital, Rockland
Rumford Community Hospital
Redington Memorial Hospital, Skowhegan
Sisters Hospital, Waterville
Thayer Hospital, Waterville
Miles Memorial Hospital, Damariscotta
Franklin County Memorial Hospital, Farmington
St. Andrews Hospital, Boothbay Harbor

MARYLAND

Dr. Hugh Young to Retire.—Dr. Hugh H. Young, professor of urology, Johns Hopkins University School of Medicine, Baltimore, and director of the Brady Urological Institute of Johns Hopkins Hospital, Baltimore, will retire at the end of the present academic year, June 30, with the title professor emeritus of urology. He will retain offices in the Brady Institute. Dr. Young graduated at the University of Virginia Department of Medicine, Charlottesville, in 1894. He has been associated with Johns Hopkins since 1895. In 1909 he was president of the American Association of Genito-Urinary Surgeons and of the American Urological Association and of the Medico-Chirurgical Faculty of Maryland in 1911. In 1917 Dr. Young was director of urology of the American Expeditionary Forces, becoming senior consultant in 1918. In 1929 he was named chairman of a state aviation committee which had been provided for by the legislature. In 1941 he was one of four recipients of the first award of the septennial prize of the Amory Fund for contributions to treatment and cure of diseases of the genitourinary system. The fund is distributed through the American Academy of Arts and Science.

MISSOURI

Dinner for Honorary Members.—The Jasper County Medical Society recently gave a dinner for its honorary members, Drs. Robert L. Neff, Robert M. James and William S. Loveland, Joplin, and Everett Powers, Carthage. Dr. William R. Gaddie, Duenweg, also an honorary member, died on January 11.

The Carman Lecture.—Dr. Leo George Rigler, professor of radiology, University of Minnesota Medical School, Minneapolis, delivered the annual Russell D. Carman Lecture in St. Louis, February 24, under the auspices of the St. Louis Society of Radiologists. His subject was "Roentgenological Diagnosis of Acute Abdominal States."

Memorial for Pioneer Physician.—On March 28 a granite headstone was unveiled at the grave of Dr. Joseph Nashe McDowell in Bellefontaine Cemetery. The stone was made possible by the contributions from about two hundred physicians and is a memorial from the class of 1895 of Missouri Medical College, St. Louis. The stone was unveiled by Mrs. Rebecca Duane Mastin, daughter of Dr. and Mrs. Edward V. M. Mastin, St. Louis, and great-great-granddaughter of Ephraim McDowell, the uncle of Joseph Nashe McDowell. Philip A. Shaffer, Ph.D., dean of Washington University,

School of Medicine, and George R. Throop, Ph.D., chancellor of the university, spoke at the ceremonies. Dr. McDowell came to St. Louis from Cincinnati, where he had been associated in the Cincinnati College of Medicine. He established the medical department of the Kemper College, later changed to the Missouri Medical College.

NEBRASKA

Personal.—Dr. James A. Burford has resigned as superintendent of the Nebraska Institution for Feeble-minded at Beatrice. Harold Peterson, secretary of the state board of control, is the new superintendent.—Dr. Charles L. Falmesstock, Lincoln, was appointed supervisor of the state WPA public health projects on February 1.

Course on Obstetrics and Pediatric Care.—A series of lectures on obstetrics and pediatrics will be held at different centers throughout the state from April 13 to April 24 under the auspices of the state medical association and the state department of health. Lecturers will be Drs. Norman R. Kietzschmar and Harry L. Towlsey, associate professors of obstetrics and pediatrics, respectively, University of Michigan Medical School, Ann Arbor. The series will open in Alliance on April 13 and continue at the following places: Scottsbluff, April 14; North Platte, April 15; McCook, April 16; Grand Island, April 17; York, April 20; Fremont, April 21; Norfolk, April 22; Nebraska City, April 23; and Falls City, April 24.

NEW JERSEY

Immunization Program.—March 30 marked the start of a program among preschool children in Newark for the administration of a serum designed to provide simultaneous immunization against diphtheria and whooping cough, according to the *New York Times*. Trial tests for a period of eighteen months carried out by Dr. Henry Simon, head of the respiratory bureau of the city department of health, were said to be beneficial to 840 children. The *Times* reported that there have been no deaths from diphtheria in Newark during the last two years during the city's concentrated immunization program. Among the 2,000 children afflicted with whooping cough annually there are an average of eight deaths. The service is to be free but parents desiring to do so may take the children to family physicians.

NEW YORK

Course on Sulfonamide Therapy.—The Medical Society of the State of New York and the state department of health have arranged a course of three two-hour sessions on sulfonamide therapy for the Orange County Medical Society, to be given at the Elizabeth A. Horton Memorial Hospital, Middletown. On May 12 Drs. Alexander D. Langmuir, Peeks, kill and Frank Glenn, New York, will discuss "Behavior of Sulfonamides in the Body and Principles for Their Use" and "Local and Internal Use of Sulfonamides in Surgery." On May 19 Drs. Thomas F. Laurie, Syracuse, will speak on "Treatment of Genitourinary Infections in the Male" and Robert Gordon Douglas, New York, Sulfonamides in Obstetrics and Gynecology." On May 26 Drs. L. Whittington Gorham, Albany, and Harry Bakwin, New York, will discuss "Treatment of Pneumonia" and "Treatment of Meningitis" respectively.

New York City

The Seventh Harvey Lecture.—Dr. Philip D. McMaster of the Rockefeller Institute for Medical Research will deliver the seventh Harvey Society Lecture of the current series at the New York Academy of Medicine, April 16. He will speak on "Lymphatic Participation in Cutaneous Phenomena."

Fund for Psychiatry.—Under the will of the late Dr. Menas S. Gregory, New York University College of Medicine has received a fund of \$40,000. Twenty thousand dollars will be used to establish an annual lectureship and the remaining \$20,000 will be given toward the endowment of a professorship in the department of psychiatry. Dr. Gregory was for many years professor of psychiatry at the medical school.

Musical Society.—The Doctors Musical Society of Brooklyn will offer its sixth concert at the Grand Ballroom of the Hotel St. George, Brooklyn, May 13, under the auspices of the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn. Committee on Social Activities in cooperation with the Hotel St. George. Proceeds will go to the mobile canteen unit for Brooklyn. Myron Leuter will conduct.

OHIO

Physician Named to Welfare Post.—Dr. Charles T. Dolezal, assistant clinical professor of medicine, Western Reserve University School of Medicine, has been appointed welfare director of Cleveland. According to the state medical journal, this is the first time that a physician has been named to the position. Dr. Dolezal graduated at Western Reserve in 1926.

Dr. Bigelow Named Acting Dean at Ohio State.—Dr. Leslie L. Bigelow, clinical professor of surgery at Ohio State University College of Medicine, Columbus, has been appointed acting dean of the school. He succeeds Dr. Hardy A. Kemp, dean since Sept. 1, 1941, who as a major in the medical reserve corps of the U. S. Army has been called into active service at the Army Medical School, Washington, D. C. Dr. Bigelow has been a member of the faculty at Ohio State since 1914; he was named to his present professorship in 1938. He formerly served as president of the Columbus Academy of Medicine and the Ohio State Medical Association. Dr. Kemp will teach tropical diseases at the Army Medical School, it is reported.

State Medical Meeting in Columbus.—The Ohio State Medical Association will hold its ninety-sixth annual session at the Neil House, Columbus, April 28-30, under the presidency of Dr. Harry V. Paryzek, Cleveland. The program includes the following out of state speakers:

- Dr. Chester S. Keefer, Boston, Chemotherapy.
- Dr. Frederick A. Collier, Ann Arbor, Mich., Simplified Parenteral Feeding Before and After Operation.
- Dr. Richard H. Freyberg, Ann Arbor, Recent Trends in the Treatment of Rheumatoid Arthritis.
- Dr. William G. Lennox, Boston, New Light on Epilepsy and Migraine.
- Dr. Alton E. Braley, New York, Sulfonamides in the Treatment of Ocular Infections.
- Dr. Tinsley R. Harris, Winston-Salem, N. C., Hypertension: Some Recent Advances.
- Dr. Leonard G. Rowntree, Colonel, M. C., U. S. Army, Washington, D. C., Health and National Defense.
- Edmund V. Cowdry, Ph.D., St. Louis, Factors in Aging of the Human Body.
- Dr. Frank H. Krusen, Rochester, Minn., Physical Therapy in General Practice.
- Dr. Merrill C. Sosman, Boston, Observations on Curable Heart Disease.
- Dr. John H. Lawrence, Berkeley, Calif., Clinical Applications of Artificial Radioactivity.

A feature of the meeting will be "quiz discussion" sessions covering chemotherapy, preoperative and postoperative care, nervous and mental diseases, nutrition and national defense, technical phases and clinical applications of plasma transfusions, general medical problems and physical therapy, including x-ray, radium and radioactive isotopes. There will be a continuous program of medical motion pictures. At the annual banquet Thursday evening Roderick Peattie, Ph.D., geographer and author and professor of geography, Ohio State University, Columbus, Ohio, will speak on "The Significance and Limitations of Geopolitics." The woman's auxiliary to the state medical society will meet on April 29 and 30. Other meetings will include the Ohio section of the American College of Chest Physicians, April 29, and a joint meeting of the Ohio Society of Anesthetists and the Ohio section of the American Society of Anesthetists, Inc., April 30.

OKLAHOMA

State Medical Meeting in Tulsa.—The Oklahoma State Medical Association will hold its fiftieth annual session at the Coliseum, Tulsa, April 22-24, under the presidency of Dr. Finis W. Ewing, Muskogee, and with the Tulsa County Medical Society acting as host. Included among the speakers will be the following:

- Dr. Charles C. Dennis, Kansas City, Mo., Treatment of Pregnant Syphilitic Women and the Results of Treatment.
- Dr. George R. Hermann, Galveston, Texas, Functional Heart Disorders, Including the Soldier's Heart.
- Dr. Morris Edward Davis, Chicago, The Endocrines in Obstetrics and Gynecology.
- Dr. Algernon B. Reese, New York, Exophthalmos Associated with Thyroid Disease.
- Dr. John C. Burch, Nashville, Tenn., Physiologic Approach to Gynecology.
- Dr. Hugh L. Dwyer, Kansas City, Mo., Protection of Children Against Tuberculosis.
- Dr. Robert L. Sanders, Memphis, Tenn., Carcinoma of the Colon.
- Dr. Titus H. Harris, Galveston, Complications Following the Use of Dilantin.
- Dr. Thomas Leon Howard, Denver, Malignancy of the Bladder and Prostate with Reference to New Methods of Treatment.

The guest speakers will address both sectional and general sessions. A feature of this year's meeting will be a round table on sulfonamide therapy, in which all the guest speakers will participate.

PENNSYLVANIA

Personal.—Dr. Jeremiah Fletcher Lutz and Dr. Francis R. Wise of York have been appointed chairman and co-chairman, respectively, of Emergency Medical Service of York and York County.

Philadelphia

Immunization Program in Scarlet Fever Outbreak.—New clinics for the immunization of children against scarlet fever are being established throughout the city to cope with the disease which has been epidemic for several weeks, newspapers report. The city department of health has augmented its staff with the appointment of Dr. Harry Strieb as immunologist. Two other physicians and ten nurses have also been added to assist in the outbreak. Fifty-five new cases on March 21 brought the total for the year up to 2,036 and for the month of March to 878.

Dinner to Dr. Babcock.—Dr. William Wayne Babcock, since 1903 professor of surgery and clinical surgery, Temple University School of Medicine, was guest of honor at a dinner, March 26, given by citizens of Philadelphia, trustees of Temple University and the faculty and alumni of the medical school as an "expression of appreciation of Dr. Babcock's accomplishments and contributions to Temple University, Temple University Medical School, and the city of Philadelphia." Participating in the dinner were the Babcock Surgical Society, the Nurses Alumni Association and the entire student body of the medical school. Dr. Babcock has been affiliated with various institutions in Philadelphia since 1895.

Society News.—Dr. Francis L. Lederer, Chicago, discussed "Signs and Symptoms of Labyrinthitis—Their Surgical Implications" before the Philadelphia Laryngological Society March 10.—The Philadelphia Psychiatric Society was addressed, March 13, by Dr. Francis J. O'Brien, New York, on "Psychiatry in Education."—The Pathological Society of Philadelphia was addressed, February 12, by Drs. Baldwin H. E. W. Lucke and Hans G. Schlumberger on "Tumors in Cold Blooded Animals as Experimental Material for Studies on Neoplasia" and Dr. Dale Coman, "Human Neoplasia in Tissue Culture." All are of Philadelphia.—Dr. Louis Chargin, New York, among others, addressed the Philadelphia County Medical Society, February 11, on "Massive Dose Arsenotherapy in Syphilis."

TENNESSEE

New Professor of Pediatrics.—Dr. Walter Henry Maddux, now completing graduate studies at Yale University School of Medicine, New Haven, has been appointed professor of pediatrics at Meharry Medical College, Nashville, newspapers report. Dr. Maddux graduated at Rush Medical College, University of Chicago, in 1923.

State Medical Meeting in Memphis.—The Tennessee State Medical Association will hold its annual session at the Peabody Hotel, Memphis, April 14-16, under the presidency of Dr. Hiram A. Laws, Chattanooga. According to a preliminary program, the following guest speakers will participate:

- Dr. Robert J. Reeves, Durham, N. C., Diagnosis and Treatment of Pulmonary Fungus Infection.
- Dr. James S. Mc Lester, Birmingham, Ala., Nutrition and Defense.
- Dr. Carl M. Peterson, Chicago, Secretary, Council on Industrial Health, American Medical Association, Industrial Health and the Practicing Physician.
- Dr. C. Anderson Aldrich, Winnetka, Ill., Ancient Processes in a Scientific Age—Feeding Aspect.
- Dr. Fred Rankin, Lexington, Ky., President-Elect, American Medical Association (subject not announced).
- Dr. Edgar H. Greene, Atlanta, Ga., The Procurement and Assignment Service.

Other groups meeting simultaneously with the state society are the Tennessee Academy of Ophthalmology and Otolaryngology and the Tennessee State Pediatric Society. Dr. William A. Garrott, Cleveland, will be guest speaker before the ophthalmologic group.

TEXAS

Medical Officer Prisoner of War.—Dr. Gustav Mason Kahn, Galveston, medical officer, U. S. Navy, stationed at Lake Island, is reported to be a prisoner of war, according to the Galveston News. Dr. Kahn graduated at the University of Texas Faculty of Medicine in 1932.

Changes of Health Personnel.—Dr. Paul L. Vermer, Gilmer, has been named health officer of Upshur County. Dr. Stephen W. Wilson, Gilmer, was recently chosen director of the new city health unit at Atlanta. Dr. Hatch W. Cummings is the new health officer of Hearne.—Dr. William B. Patterson, Brownfield, is the new director of the five county health unit serving Dawson, Hockley, Yoakum, Gaines and Terry counties, with headquarters in Brownfield.

GENERAL

Special Society Election.—Dr. Herman C. Pitts, Providence, R. I., was elected president of the American Society for the Control of Cancer at its annual meeting in New York in March. Other officers are Dr. Frank E. Adair, New York, vice president; Dr. Cornelius P. Rhoads, New York, secretary; James H. Ripley, New York, treasurer, and Clarence C. Little, Sc.D., Bar Harbor, Maine, managing director.

Meeting of Gastroscopic Club.—The recently organized American Gastroscopic Club will hold its first annual meeting in Atlantic City, June 7, with headquarters at the Hotel Claridge, when the following program will be presented:

- Dr. Rudolf Schindler, Chicago, Introduction—On Chronic Epigastric Distress and on the Anatomic Foundation of Chronic Gastritis.
- Dr. Crawford F. Barnett, Atlanta, Gastroscopic and Clinical Symptoms of Chronic Superficial-Atrophic Gastritis.
- Dr. Edward B. Benedict, Boston, Gastroscopic and Clinical Symptoms of Chronic Hypertrophic Gastritis.
- Dr. George B. Eusterman, Rochester, Minn., Clinical Significance of Chronic Gastritis.
- Dr. Seymour J. Gray, Chicago, Epigastric Symptoms in Alcoholics With and Without Gastritis.
- Dr. John Tilden Howard, Baltimore, Gastroscopic Findings in Cholecystectomy Patients.
- Dr. John L. Kantor, colonel, M. C., U. S. Army, New York, Significance of Chronic Dyspepsia for the Army in World War I.
- Dr. Rubin L. Gold, captain, M. C., U. S. Army, San Francisco, Gastroscopic Findings in Chronic Dyspepsia in the Army.
- Dr. Frank B. McGlone, captain, M. C., U. S. Army, Denver, Incidence of Gastritis in Draftees, Soldiers and War Veterans.

Courses in Kenny Treatment of Paralysis.—A series of courses in the Kenny method of the treatment of early poliomyelitis will be conducted in Minneapolis under the supervision of Dr. Miland E. Knapp, director of the department of physical therapy, University of Minnesota Medical School, Minneapolis. The courses will be financed by the National Foundation for Infantile Paralysis. They have been arranged for physicians, registered physical therapy technicians, nurses with responsible positions in teaching institutions and nurses in key positions in large contagious disease hospitals. The classes will be repeated at various times in the next six to twelve months. The physicians' course is to be of one week's duration and limited to fifteen physicians although it will be repeated from time to time as the demand requires. The course for nurses from contagious disease hospitals is also of one week's duration. The course for registered physical therapy technicians, preferably technicians who have also had nurses' training, and for nurses in teaching institutions is of two to six months' duration. It is recommended that each institution contemplating the inclusion of the Kenny treatment in its program send a physician, a technician and a nurse for training. Inquiries concerning fees and dates of courses should be sent to the Director, Center for Continuation Study, University of Minnesota, Minneapolis.

Report of Rockefeller Foundation.—More than \$9,000,000 was appropriated by the Rockefeller Foundation during 1941, mainly in the six major fields of public health, medical sciences, natural sciences, social sciences, humanities and program in China. The work in public health received the largest appropriation, \$2,450,000. Medical sciences was second with \$2,120,000. Of the money spent, 74 per cent was for work in the United States and 26 per cent for work in other countries. The largest appropriation made by the foundation in 1941 was \$600,000 toward the endowment of the department of public health and preventive medicine of Cornell University Medical College, New York. During the year the Rockefeller Foundation supported four hundred and twelve fellowships for citizens of thirty-four different countries at a cost of \$594,000; one hundred and eighty-one persons studied in countries other than their own. Fellowships for Latin Americans increased by 52 per cent over 1940; fellowships for Europeans, already at a low figure in 1940, decreased by 40 per cent. The fields represented in the two hundred and seventy-six fellowships administered directly by the foundation were public health one hundred and seven, public health nursing twenty-two, medical sciences fifty-three, natural sciences eighteen, social sciences twenty-six, humanities forty-one and the program in China nine, not including local fellowships for study in China. Two thousand three hundred and seventy-eight applications for financial aid were declined.

The foundation distributed 1,938,300 doses of yellow fever vaccine to the United States government and 1,972,380 doses to Africa. Including the total that went to India, Brazil and Singapore, the foundation gave a grand total of 4,260,680 doses of its own manufactured yellow fever vaccine. At the request of the army and navy, several million more doses will be distributed this year. Reflecting the action of the war on its activities, the foundation closed its Paris office in June 1940 and its Lisbon office in July 1941. There are now no founda-

tion representatives on the continent of Europe, but an office is being maintained in London. Late in 1940 the Far Eastern office was moved from Shanghai to Manila. Peiping Union Medical College was closed by the Japanese authorities early in 1942 and the leading members of the staff were interned.

Emphasis is being placed on studies of malaria, typhus and yellow fever. In Trinidad, where malaria is the most urgent health problem, a study is being made in the civilian population. Another malaria project is on the Burma Road. A laboratory has been established directly on the road, and under war circumstances the project has encountered difficulties. A new technic was developed for measuring antibodies in the blood before and after vaccination for influenza, and eleven different types of vaccines have been prepared and tested in human volunteers. Special studies have been carried out in nutrition. One project was instituted in England in 1941 with the Ministry of Health and the Oxford Nutrition Survey.

The foundation gave \$110,000 to the American Library Association to forestall the growth of serious gaps in the files of American scholarly journals in the libraries of war affected countries. A grant in aid was also given to expedite the flow of similar material from Europe to the United States.

The foundation appropriated \$168,000 to the National Research Council to establish the Welch Fellowships in honor of the late Dr. William Henry Welch, Baltimore. This program will support a plan of senior fellowships in internal medicine, offering long training and adequate stipends to carefully selected men from 30 to 40 years of age. Stipends will not exceed \$6,000 annually; in addition, allowances not to exceed \$1,000 a year will be made for equipment and technical assistance. The first appointment will be for a period of three years, and subsequent appointment will be at the discretion of the council up to a total term of six years for each fellow. Fellowship holders will be free to move to the clinics best equipped to train them.

To develop a center in the United States for the study of tropical diseases, the foundation in 1941 gave \$200,000 to the Tulane University of Louisiana School of Medicine, New Orleans.

LATIN AMERICA

New Public Health Journal.—The *Revista do Instituto Adolfo Lutz*, the official journal of the Central Laboratory of Public Health of São Paulo, has made its appearance. The first issue was dated July and the second December 1941. Dr. José P. Carvalho, Lima, is editor of the journal. The institute which the new publication serves bears the name of the late Adolfo Lutz, Rio de Janeiro, who for many years was the director of the Institute Bacteriológico of São Paulo, which was later transformed into the Central Laboratory of Public Health.

National Tuberculosis Committee.—A National Committee was recently organized in Argentina for the government campaign against tuberculosis. It will have headquarters in Buenos Aires and will direct and intensify the national crusade against tuberculosis. It will also manage the various problems related to the control of the disease in the country. Drs. Alejandro A. Raimondi and Rodolfo A. Vaccarezza, professors at the Faculty of Medicine of the University of Buenos Aires, were appointed president and secretary, respectively, of the National Committee against tuberculosis.

CORRECTIONS

St. Francis Hospital.—In the Hospital Number of THE JOURNAL, March 28, page 1088, the symbol * indicating approval for residency, intended for St. Francis Hospital, Wichita, Kan., was mistakenly placed on St. Francis Hospital, Topeka, Kan.

Milk Borne Outbreak of Septic Sore Throat.—In a news item in THE JOURNAL, March 28, page 1151, reporting an outbreak of septic sore throat, the last sentence of the story should have read: Strains of hemolytic streptococci belonging to Lancefield serologic group A were isolated from the milk of the injured cow, from throat cultures from the milk handler and from a number of patients.

Barre City Hospital, Barre, Vermont.—In the Hospital Number of THE JOURNAL, March 28, page 1126, Barre, Vermont, and its hospital facilities were by typographical error placed under Utah. Barre, a city of 10,909 population in Washington County, has the Barre City Hospital, gen., N. P. Acon., 60 beds, average census of 50; 15 bassinets; 322 births; 2,043 admissions; approved by American College of Surgeons and State Board of Nurse Examiners. Also Washington County Tuberculosis Sanatorium, state owned; 47 beds; average census of 42; 64 admissions. Both fully registered and not "ated" institutions.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Feb. 21, 1942.

Reduction in the Medical Staff of Hospitals

The minister of health has decided to reduce the medical staff of hospitals so as to provide more medical officers for the fighting forces. Whole time members of the staff are to be reduced by 15 per cent in London and by 10 per cent in the provinces. In the teaching hospitals the reduction will be smaller. In a circular the minister points out that this lowering of the numerical standard of staffing in hospitals calls for a maximum degree of cooperation between hospitals in time of pressure. He has therefore instructed his medical officers in each civil defense region to work out plans whereby hospitals heavily pressed by air attack or exceptional incidence of sickness in the locality can be given relief by other hospitals. Some arrangements of this kind already exist but the minister wants them to be general and on a clearly defined basis. He has in mind the allocation of specified officers in each hospital for temporary transfer in case of need. The period of transfer would usually be short, perhaps not more than a week. The arrangement should also include nurses.

American Hospital Built to Withstand Air Raids

The new Churchill Hospital is to be opened at Oxford. It will be administered by a group of American surgeons who arrived in England on the first day of the air raids on London. The hospital was built in 1941 and therefore is the first to be built with the horrors of modern warfare in mind. It is so designed that a bomb could do no great damage to the hospital as a whole. The wards are built round a courtyard, each ward having its own air raid shelter. Six hundred patients can be accommodated. The staff comprises twelve American doctors and fifty American and Canadian nurses. Its main function will be reconstruction, of which the two branches will be orthopedic and plastic. A medical service and other types of surgery will be provided as necessity arises. After the war it is intended, if possible, to keep the hospital as a permanent American hospital in relation with the Oxford Medical School. It is hoped that a similar British organization may be initiated in relation with a university in the United States.

War Injuries of the Eye

The indiscriminate bombing of cities has produced many cases of injury to the eye. At a meeting of the Section of Ophthalmology of the Royal Society of Medicine Mr. T. M. Tyrrell opened a discussion on the subject. He found that peace time methods of treatment did not apply well in war time. Some of the cases he had been unable to deal with at once and then learned the possibility of leaving a badly injured eye for twenty-four hours and getting a good result. He found in several cases that it was easier to deal with those which had to wait, and consequently he purposely began to leave patients unoperated on and found that results were apparently better. In the past he had been impressed by the degree of shock and restlessness of patients with perforating injuries and the need for a good seventh nerve block before thorough examination or operation. After the lapse of time the shock passes off and the patient is in a better condition to stand operation. This applies with even more force to air raid casualties in which there is more shock than in civil cases of eye injury. The dirt appears to have been blown deep into the skin and the conjunctival sacs are usually filled with a slimy mudpie of mucus and dirt. It is well to subject all these eyes to two or three hourly irrigations with an alkaline lotion before any

operative intervention and at the time of operation to irrigate the conjunctival sac with 2 per cent silver nitrate long enough to produce a slight white film over the cornea. This forms a protective coat over particles which may be embedded in the cornea or conjunctiva and helps to prevent infection.

In nonpenetrating injuries all glass must be picked out of the conjunctival sac. Nearly all wounds of the lids become infected. Mr. Tyrrell cleans them with hydrogen peroxide and cuts out all obviously damaged tissue unlikely to survive. When there are multiple corneal foreign bodies he does not touch them. These patients are soon comfortable if the pupils are kept well dilated with oily atropine 0.5 per cent and later with "paroline drops." The foreign bodies rapidly fall out, and any left can be picked out later.

Glass injuries are the chief bugbear of air raids. To prevent them, firemen and fire watchers should have a protective visor. It is very difficult to see glass even with a slit lamp and more difficult to extract. Fortunately in most cases glass works its way out even from the depths of the wound. Most glass injuries are so liberally peppered with small fragments that any attempt to roentgenograph them in looking for an intraocular fragment fails because of the cloud of other small pieces. In cases of a piece of glass lodged in the eye which shows no tendency to come out, the only indication for operation is interference with vision in an otherwise useful eye. Mr. Tyrrell has had about twenty severe glass injuries and has had to remove ten eyes too pulped to be saved. In the majority of the others, glass had perforated the cornea or sclera and fallen out again, and all that was necessary was a clean up, iridectomy and conjunctival flap.

The Effect on the Kidney of Limb Compression

In a previous letter a new syndrome—renal failure produced by prolonged compression of limbs by debris of buildings fallen during air raids—was reported. In a discussion at the Section of Surgery of the Royal Society of Medicine the president, Mr. E. Rock Carling, said that so far the war had furnished few new surgical problems, but an outstanding observation was the grave and often fatal damage to the kidneys after prolonged compression of the limbs. It was impossible to believe that a similar syndrome had not been associated with injuries in civil life, such as mine accidents. Little had appeared on the subject in English literature, but cases had been found in German literature.

Dr. J. McMichael said that the breakdown of autolytic products from dead or dying muscle seemed to be the main factor in damaging the kidneys. Some chemical substance was liberated and poisoned the tubule cells. There was also a tubule blockage, possibly from precipitation of myohemoglobin in the tubes. In crush injuries the kidney should be thought of from the first. The mistake had been made of waiting until about the third day, when renal damage was already severe, before treating the renal condition. It should be impressed on rescue parties that in persons pinned down by the limbs under wreckage the danger was renal failure. Therefore it was important to insure good diuresis, particularly about the time the injured were due to be released from pressure. Every effort should be made by means of abundant warm drinks to secure a good urinary flow. The diuresis would dilute the chemical substances within the renal tubules and perhaps prevent precipitation of myohemoglobin casts. Once the victim was released the circulation was likely to be flooded with toxic products, and therefore a more rational method of treatment was necessary. He did not think that any severe additional damage would be produced by the immediate application of a tourniquet. It should be applied to the limb above the site of crushing. When the patient reached the hospital the circulation through the limb should be restored only when good diuresis was established. Gradual release of the circulation might be attempted
